# Measurements of Neglected Double Stars: November 2014 Report 

Joseph M. Carro<br>Cuesta College, San Luis Obispo, California

#### Abstract

This article presents measurements of 30 neglected double stars. The stars were selected from the Washington Double Star Catalog published by the United States Naval Observatory. The photographs were taken by a remote telescope. The measurements were done by the author.

## Methodology

The photographs were taken using a telescope located in the Canary Islands near the west coast of Africa. The telescope is located at an elevation of 2,300 meters. The instrument has a focal length of $3,910 \mathrm{~mm}$, an aperture of 356 mm , and is a Celestron unit of Schmidt-Cassegrain design. The observatory, which is called SLOOH, is a part of the Institute of Astrophysics. The methods used to calibrate the instruments of the SLOOH Observatory are unknown to this author.

The camera used most frequently was a CCD SBIG 10XME, but some photographs were taken using a CCD SBIG 2000XM.

The photographs were analyzed by the author using the programs CCD Soft v5 and SKY 6. The two programs are products of Software Bisque.

After accumulating the photographs, averages were calculated for the position angles and separations. All of the star patterns were compared with the data from ALADIN (part of the SIMBAD site) or with the SKY X program, to insure correctness.

After measuring each star and calculating the results, comparisons were made with the published data. The results are listed in the table. The numbers in the table represent averages of measurements, or, in the case of a single measurement, the actual value.

## Report

The following information was reported for each star: the WDS code with components, the discoverer
code, the constellation, the position angle, the separation, the date of the first observation, and, under measures by the author, the results of other authors. The number of measurements for WDS values was the number of past observations reported in the WDS prior to these current observations.

The column headings are: number of the Washington Double Star and components, DC = Discovery Code, PA $=$ position angle, Sep $=$ Separation, Mts $=$ number of measurements, Con $=$ Constellation, and the first observation date.

## Acknowledgements

Grateful appreciation is extended to Russell Genet for his guidance and to Thomas Smith for his support.

This research made use of the SIMBAD database operated at CDS, Strasbourg, France, and the Washington Double Star Catalog maintained by the United States Naval Observatory.

# A New Visual Binary System in Auriga 

Abdul Ahad<br>Luton, Bedfordshire, United Kingdom<br>aa_spaceagent@yahoo.co.uk

#### Abstract

A new visual binary system is reported in Auriga, currently not listed in the WDS catalog. The components have been determined to be a pair of G-type main sequence stars that lie close to a least squares negative exponential curve, which places the pair at a distance of some 300 to 500 ly from Earth.

## Introduction

I had first noticed this pair on the moonless night of September $24^{\text {th }} 2014$ whilst sweeping the star fields surrounding the red-tinted carbon star UU Aurigae. My initial reaction was how aesthetically beautiful this pair had seemed, all so neatly presented in the eyepiece with a small $\Delta \mathrm{m}$ and that the components were not too widely spaced apart. It wasn't until October $21^{\text {st }} 2014$ that I had determined the system was in fact a true CPM binary. That same night of October 21st, once the clouds had shifted, the skies turned out to be pristinely clear with steady seeing conditions and so I set about finding the pair again in my 120 mm refractor. They were easy to spot about $2.9^{\circ}$ to the lower left of UU Aurigae, as shown in Figure 1.

I then had the pleasure of making a drawing of the field, and this is shown in Figure 2.

The components of this binary have Tycho 2 designations: TYC 2443-146-1 and TYC 2443-337-1, located in the sky at 2000 ICRS: $063848.17+353629.6$ (J2000.0), and they are of UCAC4 apparent visual magnitudes 10.17 and 11.39 , respectively.

## Observations and Analysis

The system was later imaged using the 0.61 meter Cassegrain telescope of the Sierra Stars Observatory Network on November 3, 2014, from which the position angle and separation were deduced for epoch 2014.841:

Figure 1: Location of the new binary south of UU Aurigae

PA: $172.6^{\circ}$
Sep: 15.61"
The UCAC4 catalog [1] revealed the two stars to be sharing virtually identical proper motions, shown in Table 1.

## A New Visual Binary System in Auriga

Figure 2: Pencil sketch made with a 120 mm (4.75") refractor at a magnification of x159. The FOV is about 10 arcminutes in radius and the faintest stars are of magnitude 12.

A total proper motion, $\mu=\left(\mu_{\alpha}^{2}+\mu_{\delta}{ }^{2}\right)^{1 / 2}=37.8$ mas $\mathrm{yr}^{-1}$ was computed for the pair. Referring back to my earlier work, the use of the inverse correlation between distance and proper motion which I had first postulated in 2011 (Ahad 2011, Webb Society DSSC 19, page 48 , Table 1) to be a predictive tool for gauging astrophysical characteristics of wide double stars, was further expanded over a larger sample of stars and then fine -tuned to both a tabular, as well as a graphical, form. The latter is shown in Figure 3.

Through successive iterations and some trial and error, I derived a least-squares negative exponential to fit the centreline:

$$
y=17941 x^{-1.11}
$$

where $x$ is the distance in light-years and $y$ the total annual proper motion in milliarcseconds. It will be seen from the chart that a total PM of $37.8{\mathrm{mas} \mathrm{yr}^{-1} \text { places }}^{\text {P }}$ this new Auriga binary at a distance range of some 300 to 500 light-years ( 90 to 150 parsecs) from Earth. The curve in Figure 3 can, in fact, be used as a general reference tool to ascertain a more statistically rigorous distance estimate for both single and multiple stellar systems in cases where trigonometrical parallaxes have either not been determined at all, or have been poorly de-

Table 1: Proper Motion of Components

|  | $\boldsymbol{\mu}_{\alpha}$ <br> mas $\mathbf{y r}^{-1}$ | Error <br> mas $\mathbf{y r}^{-1}$ | $\boldsymbol{\mu}_{\delta}$ <br> mas $\mathbf{y r}^{-1}$ | Error <br> mas $\mathbf{y r}^{-1}$ |
| :---: | :---: | :---: | :---: | :---: |
| Primary | +7.7 | $\pm 1.0$ | -36.9 | $\pm 0.9$ |
| Companion | +7.8 | $\pm 0.8$ | -37.1 | $\pm 1.1$ |

Figure 3: The negative exponential determined by the author to fit a least-squares regression curve, showing statistically significant distance ranges for both the new binary and UU Aurigae.
termined. Whereas trigonometrical parallaxes can be highly uncertain for stellar systems going into great distances exceeding of the order of 1000 light-years or more, it is the author's personal experience that the proper motion errors can often be much more manageable way beyond such distance thresholds. The carbon star UU Aurigae is a good candidate case to illustrate this point. UU Aurigae is in its own right a 'Washington Double Star' (WDS 06365+3827), though not a binary, attended by a wide unrelated companion of magnitude 11.77. Distance estimates for UU Aurigae A tend to be highly uncertain in the literature. Values typically range from 1600 to 1800 light-years, with a $\pm 800$ light-year error margin. The measured parallax of UU Aurigae is 1.80 mas, with a high uncertainty of $\pm 0.81$ mas ( $45 \%$ error), whereas the proper motion of this star is stated as
 $5 \%$ error). In these circumstances, it would make more sense to use the proper motion to estimate the distance of UU Aurigae rather than its unreliable parallax. Hence, a more reasonable estimate for the distance of UU Aurigae would perhaps be in the 400 to 700 lightyear distance range, as shown by the red dotted line in Figure 3.

From the 2MASS catalog [2] we find J and K magnitudes, color indices (J-K), and likely spectral types [3] for the components of this new CPM binary as shown in Table 2.

Fitting the apparent visual magnitudes of the components of 10.17 and 11.39 to average absolute magnitudes for a pair of G1V + G8V stars in the distance modulus equations, we project spectral distances of 405

## A New Visual Binary System in Auriga

Table 2: 2MASS photometry, color indices, and spectral types

|  | J-mag | K-mag | Color Index (J-K) | Spec Type |
| :---: | :---: | :---: | :---: | :---: |
| Primary | 9.157 | 8.836 | +0.32 | G1V |
| Companion | 10.229 | 9.859 | +0.37 | G8V |

ly and 428 ly, respectively, for the A and B components of this Auriga binary. These distances are close enough to one another and fit well within the 300 to 500 ly distance range derived earlier from proper motions, hence the whole scenario proves this to be a visual binary system with gravitationally connected components.

# Double Star Measurements for 2011 Part 2 

Frank Smith<br>20 Coburn Way, Jaffrey, NH 03452<br>fhasmith@frankandluann.net

#### Abstract

I report 65 measurements of binary systems from 2011.772 to 2011.774. The observations were conducted with the T11 robotic telescope located at the iTelescope Observatory, Mayhill, NM, USA . Discussion includes notes on a number of the observed doubles. Information about instrumentation and methodology and results are included.

## Introduction and Instrumentation

I have been imaging double stars for a number of years using the equipment at iTelescopes remote observatory.

The program of measuring the visual doubles used the T11 telescope in Mayhill, NM. The instrument is a Planewave 20 in Dall-Kirkham Astrograph with a focal length of approximately 2280 mm . The CCD camera is a FLI ProLine PL11002M with 9 um square pixels. The field of view is $36.2 \times 54.3$ arc-mins. The OTA is mounted on a Planewave Ascension 200HR.

The instrument is capable of quickly and accurately slewing to a selected double star. The system takes about one minute to cycle through an exposure and save the resulting image in a FITS format. Taking 5 to 6 exposures per double star allows 6 doubles to be imaged per hour. The relatively short focal length of this system restricts measurements of doubles to pairs > 10 arc-seconds in most cases.

## Methods

Imaging was done by entering the coordinates of the double into the robotic telescope's web interface. A test exposure was done and checked for centering and proper exposure. If all was well, an exposure run of 5
to 7 images through a clear filter was done for each pair. Exposures typically ran about $10-15$ seconds for 10-13 magnitude doubles. After the observing session was completed, the images were retrieved from an ftp site provided by the iTelescope observatory.

Each image in the exposure sequence was examined and any trailed or sub-par images were discarded. MOP Canopus (Warner, 2006) was used to reduce the images. Any image for which the software could not reach a plate solution was also discarded. Canopus produces an astrometric solution to the image based on the UCAC2.0 catalog (Zacharias et all.,2004) or the MSOSC catalog (USNO and Tycho data) in areas not covered by UCAC2.0. The software measures double stars using a subroutine built into Canopus. It also produces a great amount of information about the astrometric solution. All images were copied to archival CD -ROM material and are available by request from the author. Each starting and ending image was blinkedjust in case.

## Results

Table 1 shows the results for the 65 doubles measured.

# A New Double Star in Cepheus 

T. V. Bryant III<br>Little Tycho Observatory<br>703 McNeill Road, Silver Spring, Md 20910<br>rkk_529@hotmail.com<br>Reprinted from http://mainsequence.org/html/wds/tvb7/tvb_7.html

#### Abstract

A new double star has been found in Cepheus, at 21:55:22.8 +65:01:40.8, J2000. A measurement made with the Aladin tool ${ }^{1}$ of the new double gives 15.6 arc seconds of separation and a position angle of $27^{\circ}$. The APASS ${ }^{2}$ visual magnitudes, as reported by the UCAC4 ${ }^{3}$ are 11.1 and 11.35. Historical data from the stars are listed, as are distance estimates to the pair.

A new double star has been found in Cepheus at R.A. $=21: 55: 22.8$, dec. $=+65: 01: 40.8$, J2000.The pair was found while observing STT 457, WDS ID: $21555+6519$. Using the Aladin tool, UCAC4 listed the proper motions (in milliarcseconds per year) of the pair as:

Primary pmRA: -0.5, pmDec: -5.8 .
Secondary pmRa: -0.8 , pmDec: -8.2.
This was reported to William Hartkopf ${ }^{4}$ of the US$\mathrm{NO}^{5}$, who has included it in the $\mathrm{WDS}^{6}$ as TVB 7.

The primary's UCAC4 id is 569-000007, and the secondary's UCAC4 id is $569-000094$.

Dr. Hartkopf researched the new pair and emailed me his results:
"I extracted Tycho ${ }^{7}$, UCAC4, and 2 MASS $^{9}$ measures, as well as two photographic measures from 1895 and 1903-so 5 astrometry measures spanning over a century, plus 5 additional photometry measures."

These results are shown in Table 1. Column headings in the table are defined as follows:

- Date is the date of the observation.
- Rho is the separation angle, in arc seconds.
- Errors in rho are also in arc seconds.
- Theta is the position angle, in degrees.
- Errors in theta are also in degrees.
- A mag is the magnitude of the primary.
- B mag is the magnitude of the secondary.
- FEW: Filter effective wavelength, in nanometers.
- FWHM: Full width at half maximum, in nanometers.
- Note: A "B" designates a blue magnitude,
where the filter information was not accurately known.
- Aperture: Telescope aperture, in meters.
- Obs ct: Number of observations used to generate the data.
- Sources (With publication year appended):
- WFC: From the Washington Fundamental Catalog ${ }^{10}$
- TYC: From the Tycho catalog.
- TMA: From the 2MASS catalog.
- Type: The observation's data type.
- Pa: Photographic technique with an astrograph.
- Ht: Tycho data from the Hipparcos satellite.
- E2: 2MASS data.
- Eu: UCAC data.

Based on the Wikipedia H-R diagram ${ }^{9}$ and UCAC4 blue and visual magnitudes, the primary appears to have a spectral class of A8, and the secondary F9. Assuming these stars to be main sequence dwarves, this gives them approximate absolute magnitudes of +4 and +6 . Using the well known distance modulus equation:

$$
M-m=5\left(\log _{10}(d)\right)-5
$$

where $M$ is the absolute magnitude, $m$ the apparent magnitude, and $d$ is the distance in parsecs. Solving for $d$ gives:

$$
d=10^{(m-M+5) / 5)} .
$$

Distances of 250 and 120 parsecs result from the abso-

lute magnitudes of +4 and +6 , respectively. If they are both subgiants, however, the absolute magnitudes are both close to +3 , giving a distance of about 400 parsecs.

Figure 1 is a photo of the new binary from the DSS as rendered by the Aladin Sky Atlas tool.

Note that the proper motions associated with these stars are fairly small, although rho and theta have shown little change from when the pair was first measured. It is hoped that observations from the recent Gaia mission and other subsequent measurements will establish that this pair, and many like it, are physical.

## Acknowledgements

The author wishes to acknowledge the editorial assistance of William Hartkopf, Tom Corbin, and Kathleen Bryant in making this short paper more readable.

# A New Visual Binary System in Aquarius 

Abdul Ahad<br>Luton, Bedfordshire, United Kingdom<br>aa_spaceagent@yahoo.co.uk

#### Abstract

In this paper, a new common proper motion pair is reported in Aquarius, currently not listed in the WDS catalog. From a combination of B, V, J, and K-band photometry, proper motion, and radial velocity observations, the components are shown to be part of a gravitationally connected binary system.

## Introduction

A DSS image of this pair, located at ICRS: 2059 15.95, -08 1157.6 (J2000.0), is shown in Figure 1.

The primary bears the designations HD199726 and BD-08 5534, and is of V-mag 9.78. The secondary is of an estimated V-mag of $\sim 11.8$. The pair was visually sighted and sketched with a Skywatcher Evostar 120 mm refractor at $00: 25$ UT on August 1, 2014 as

Figure 1: Digitized sky survey image of the new binary in Aquarius
shown in Figure 2.
It must be stressed, however, the faint companion was only just barely glimpsed through dark adapted

Figure 2: The new binary visually sketched at a magnification of $x 159$.

## A New Visual Binary System in Aquarius

Table 1: Proper Motions and Radial Velocities of the Components

|  | $\mu_{\alpha}$ <br> $\mathrm{mas} \mathrm{yr}^{-1}$ | Error <br> $\mathrm{mas} \mathrm{yr}^{-1}$ | $\mu_{\delta}$ <br> $\mathrm{mas} \mathrm{yr}^{-1}$ | Error <br> $\mathrm{mas} \mathrm{yr}^{-1}$ | Radial Velocity <br> $\mathrm{km} \mathrm{sec}^{-1}$ | Error <br> $\mathrm{km} \mathrm{sec}^{-1}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Primary | +15.7 | $\pm 1.6$ | +2.5 | $\pm 3.4$ | +7.98 | $\pm 1.8$ |
| Companion | +16.7 | $\pm 1.6$ | +0.0 | $\pm 1.9$ | +6.66 | $\pm 1.9$ |

eyes and using averted vision. The system was later imaged to a greater resolution using the 0.61 -meter Cassegrain telescope of the Sierra Stars Observatory Network[1] on 2014 September $4^{\text {th }}$, which enabled approximate measurements to be taken:

Position Angle: $161.1^{\circ}$
Separation: 10.58"

## Proper Motions and Radial Velocities

As mentioned in earlier papers[2], the components of a dynamically associated binary system would, in addition to displaying common proper motions, be expected to have very similar radial velocities. The primary in this Aquarius pair has a measured radial velocity of $+7.98 \mathrm{~km} / \mathrm{sec}$. Radial velocities of stars as faint as this are generally not so abundantly available, however. In recent years, efforts have been initiated to extend radial velocity measurements across broader regions of the sky and going down to fainter limiting magnitudes.

The Radial Velocity Experiment (RAVE)[3], in particular, is a multi-fiber spectroscopic astronomical survey of stars in the Milky Way using the 1.2 -meter UK Schmidt Telescope of the Anglo-Australian Observatory (AAO). From this survey, it has been possible to obtain a radial velocity measurement of the faint companion in this new Aquarius pair. This, along with UCAC4 [4] proper motions for both stars are summarized in Table 1.

We note that the PM vectors and radial velocities of both components are closely aligned, considering the small error margins in each. This is strongly indicative of a binary association between the two stars.

From Table 1, a total proper motion, $\mu$, of 16.3 mas $\mathrm{yr}^{-1}$ was computed for the pair, suggesting a distance in the region of about 400 to 700 ly from Earth [5].

## Photometry and Distance Calibration

A summary of photometric data, taken from the UCAC4 and 2MASS[6] catalogs, along with spectral classifications are shown in Table 2.

We note that the primary component already has a spectroscopically determined classification of F8V in the catalogs. The K0V classification for the secondary has been determined in this paper as follows: the "K0" part is derived from its 2MASS (J-K) color index of $+0.39[7]$ and the "V" part (main-sequence dwarf) from its apparent visual brightness and estimated distance in the region of 400 to 700 ly , inferred from proper motions ${ }^{5}$. This K0V classification for the secondary is consistent in relation to the primary's already known F 8 V classification, considering that the two stars have a $\Delta \mathrm{m}$ of 2.0 and share very similar PMs. Now F8V stars generally tend to be of absolute magnitudes of around 4.0 and K 0 V stars are generally of absolute magnitudes around 5.9[8]. Projecting spectral distances of both components on these assumptions using the distance modulus, we arrive at distances of 467 ly and 494 ly from Earth, respectively, for the A and B components.

These distances are close enough to one another and fit comfortably within the 400 to 700 ly distance range projected earlier from proper motions, again suggesting a true binary system.

## Conclusions

On consideration of the astrophysical parameters of this pair discussed in this paper, and the manner in which they all fit together, we conclude that this is a proven gravitationally-connected binary system.

# Double Star Measurements at the Southern Sky with a 50 cm Reflector and a Fast CCD Camera in 2014 

Rainer Anton<br>Altenholz/Kiel, Germany<br>e-mail: rainer.anton"at"ki.comcity.de

#### Abstract

A Ritchey-Chrétien reflector with 50 cm aperture was used in Namibia for recordings of double stars with a fast CCD camera and a notebook computer. From superposition of "lucky images", measurements of 91 pairings in 79 double and multiple systems were obtained and compared with literature data. Occasional deviations are discussed. Some images of noteworthy systems are also presented.

## Introduction

As in earlier work, the technique of "lucky imaging" was applied to reduce seeing effects in recordings of double star images by using short exposure times. With only the best frames being registered and stacked, the resolution can approach the theoretical limit of the telescope, and the accuracy of position measurements can even be better than this by about one order of magnitude. More details of the technique are, for example, described in reference [1]. In this paper, measurements on double and multiple systems, made in March/April 2014 in Namibia, are reported. Some are well documented in the literature, such that extrapolations are reasonable and can be used for calibration. For many others, however, only few data exist, and often with large scatter. The present results may help to improve the statistics.

## Instrumental

Recordings were made with a 50 cm telescope of Ritchey-Chrétien type (Alluna, Germany) at the Internationale Amateur-Sternwarte (IAS) in Namibia, which I had already used in 2012 [2, 3]. The focal length is 4.1 m . Imaging was done with a $\mathrm{b} / \mathrm{w}$-CCD camera of type "Chameleon" (Point Grey). Its small pixel size of 3.75 $\mu \mathrm{m}$ square results in a nominal resolution of 0.19 arcseconds per pixel. This was about halved with a Barlow lens, with only one exception (Acrux). A more ex-
act scaling factor was obtained with calibration stars (see Table 1 and discussion below).

Recordings were made with red or near-infrared filters to reduce seeing effects and the atmospheric spectrum, and especially when using the Barlow lens, to reduce chromatic aberration. Exposure times were varied between 0.1 msec and 350 msec , depending on the brightness and on the seeing conditions. The best frames, typically several tens up to more than one hundred, were later selected and stacked, as described earlier.

Position angles were obtained as usual by recording trails in an east-west direction, while the telescope drive was temporarily switched off.

## Results

All measurements are listed in Table 1, which is followed by individual notes. Numbering of the notes (last column at right) is with R.A. values. Names, position, and magnitude data are adopted from the WDS [4]. N is the total number of recordings. Shaded lines denote systems which were used for calibration of the image scale (see below). The residuals, delta P.A. and delta rho, refer to the trends of literature data, if sufficiently available, or for binaries, to the currently assumed ephemeris, if not otherwise stated. Main sources are the Fourth Catalog of Interferometric Measurements of Binary Stars ("speckle catalog") [5], and the Sixth

## Double Star Measurements at the Southern Sky with a 50 cm Reflector ...

Table 1: List of measurements. Systems used for calibration of the image scale are marked by shaded lines. Position angles (P.A.) are in degrees, separations (rho) in arcseconds. $N$ is the number of different recordings. Residuals delta P.A. and/or delta rho are given, when extrapolations of literature data appear reasonable. Notes with asterisks refer to figures shown below.

## Double Star Measurements at the Southern Sky with a 50 cm Reflector ...

Table 1 (conclusion): List of measurements. Systems used for calibration of the image scale are marked by shaded lines. Position angles (P.A.) are in degrees, separations (rho) in arcseconds. $N$ is the number of different recordings. Residuals delta P.A. and/or delta rho are given, when extrapolations of literature data appear reasonable. Notes with asterisks refer to figures shown below.

## Table Notes:

Terms "cpm" (common proper motion) and "relfix" (relatively fixed) refer to Burnham [7].
Asterisks in column "notes" refer to figures shown below.
05135: in Orion, binary, $P=312 y$, many speckle data.
05145: $\beta$ Orionis, "Rigel", measurement difficult, because of large difference in brightness of the components, large scatter of literature data, residuals ambiguous, rho seems to slowly increase.
05308: 32 Orionis, binary in doubt, $P=586$ y ?, "motion about rectilinear", many speckle data.
06048: in Puppis, binary, $P=464$ y.
06298: in Puppis, two binaries, $A B: P=52.9 \mathrm{y}$, many speckle data, CD: $P=101$ y. Few data for $A B-C D$, residuals ambiguous.
06423: in Puppis, few data, residuals refer to last entry in speckle catalog from 1991.
07018: in Canis major, few data with some scatter, PA increasing.
07175: in Puppis, binary, $P=82 y$, large excentricity, many speckle data.
07294: in Puppis, binary, $\mathrm{P}=729$ y ?, "premature orbit".
07430: in Puppis, binary, $P=138$ y, many recent speckle data.
07479: in Puppis, binary, $P=1332$ y ?, own measure follows recent speckle data, being close to the re-
cently revised orbit (which much longer period than previously assumed).
08221: in Puppis, binary, $P=880$ y ?, few data, only small portion of orbit documented.
08321: in Vela, few data, PA decreasing, rho about constant at least since decades. See fig. 3.
08331: in Pyxis, binary, $\mathrm{P}=136 \mathrm{y}$, apparent orbit almost circular, many speckle data, measured position deviates from ephemeris, but fits better to the trend of recent speckle data. See figs. 3 and 4.
08391: in Pyxis, binary, $P=123 y$, orbit highly inclined, many speckle data with only small scatter, but significant deviations from ephemeris. Own measure closely follows trend of recent speckle data. Residuals refer to ephemeris.
08394: in Pyxis, binary, $P=66 y$, few data.
09125: in Vela, few data, PA decreasing, rho increasing.
09307: $\psi$ Velorum, binary, P = 34 y, own measure deviates from ephemeris, but follows the trend of recent speckle data. See fig. 6.
09333: in Carina, "neglected".
09372: in Vela, PA increasing.
10036: in Carina, "neglected", few data, rho virtually constant since about a hundred years, PA increasing?

## Double Star Measurements at the Southern Sky with a 50 cm Reflector ...

10062: in Vela, binary, P = 232 y, few data. See fig. 3.
10333: in Vela, tripel, too few data, residuals ambiguous, $\mathrm{PA}(\mathrm{BC})$ increasing.
10361: in Hydra, binary, $P=210 y$, orbit well documented, recent speckle data with only small scatter suggest fairly accurate extrapolation.
10373: in Vela, close and fast binary, $P=16 y$, although measurement difficult, because companion on diffraction ring, position seems to deviate from the ephemeris, and to follow the trend of recent speckle measurements. See fig. 3.
10468: mu Velorum, binary, $P=138$ y, few data, own measure of rho as well as recent speckle data fit quite well to the recently revised orbit.
10537: in Carina, few data, residuals refer to last entry in speckle catalog from 1991.
11234: in Musca, few data, residuals ambiguous.
11247: in Centaurus, binary, $P=421$ y, few speckle data.
11286: in Centaurus, binary, $P=650$ y ?, only small portion of orbit covered, own measure follow speckle data, all deviate from ephemeris.
11366: in Hydra, relfix, cpm, few data, residuals ambiguous.
11550: in Centaurus, binary, P = 930 y ?, orbit highly inclined, only small portion documented, measured position is far off from ephemeris.
12036: in Centaurus, binary, $P=109 y$, small scatter of recent speckle data, PA and rho rapidly decreasing.
12048: in Crux, relfix, few data, dim companion x near A (~13 mag?) not listed in the WDS. See fig. 10.
12158: in Corvus, binary, $P=873$ y ?, orbit is preliminary, but recent speckle data with relatively small scatter let short term extrapolation appear reasonable.
12249: in Crux, few data, residuals ambiguous.
12260: in Corvus, binary, $P=707.6$ y ?, orbit ambiguous, highly inclined, few data.
12266: alpha Crucis, AB binary, no closed orbit determined, few data, even fewer for $A C$, residuals ambiguous. Separations of both AC and AG have increased by 2.2" or 2.3", respectively, since my last measurements in 2012, while the PA's were about the same. Imaging of component $G$ was done without Barlow, and of distant $C$ even with a reducer to increase the field of view. The corresponding scaling factors were calculated on the basis of images of $A B$, taken with Barlow.
12283: in Crux, binary, $P=2520$ y ?, orbit preliminary, few data, PA decreasing. BC not resolved.
12463: beta Muscae, binary, $P=383$ y, measured posi-
tion is lying exactly on the orbit, but deviates from the ephemeris. This seems to be shifted by about 5 years. See figs. 5a and 5b.
12567: in Centaurus, binary, $P=294$ y, measured position is close to recently revised orbit.
13038: in Virgo, binary, P = 59 y ?, orbit almost directly edge-on.
13066: in Centaurus, "neglected", PA decreasing, rho slowly increasing.
13074: in Centaurus, relfix, PA decreasing, own measure seems to follow the long time trend, despite large scatter of recent speckle data, rho decreasing since about 1950.
13149: in Virgo, binary, orbit revised in 2014, $P=122.7$ y , few data.
13325: in Musca, binary, $P=590$ y, few data, rho deviates from ephemeris, in accordance with recent speckle data.
13438: in Centaurus, few data, PA and rho decreasing.
13520: in Centaurus, binary, newly revised orbit, $P=$ 280 y, PA decreasing, rho rapidly increasing.
13535: in Centaurus, binary, $P=258$ y, few data, measured position deviates from ephemeris, similar to recent speckle data. See figs. 7a and 7b.
14077: in Centaurus, binary, $P=233$ y, measured position reasonably fits to recently revised ephemeris.
14202: in Lupus, few data, rho seems to be slowly decreasing, residuals ambiguous.
14396: alpha Centauri, AB binary, $P=79.9$ y, well documented.
14408: in Circinus, "neglected", few data, rho seems to be increasing, residuals ambiguous.
14542: in Circinus, binary, $P=288$ y, few data, own measure close to ephemeris.
14565a: in Centaurus, binary, $P=40$ y, own measure close to ephemeris.
14565b: also known as DUN 174, in Lupus, although denoted as relfix by Burnham, rho has decreased since 1826, while the PA stays about constant in the last hundred years.
14575: also known as 33 Librae, AB binary, $P=2130$ y (?), only a small portion of the orbit is documented, but this is on a long stretch, which can fairly accurately be extrapolated to the near future.
14587: also known as 59 Hydrae, binary, $P=429$ y, measured position fits well both the ephemeris and the trend of recent speckle data. See fig. 3.
15051: pi Lupi, PA slowly decreasing.
15140: in Lupus, "neglected", PA decreasing, while rho about constant.
(Continued on page 86)

## Double Star Measurements at the Southern Sky with a 50 cm Reflector ...

15160: in Libra, binary, $P=156 \mathrm{y}$, large scatter of recent PA (speckle) data.
15192: in Libra, few data, PA decreasing.
15234: gamma Circini, binary, $P=270 y$, while the measured PA is close to the newly revised ephemeris, rho is slightly off.
15295: in Circinus, "neglected", PA increasing.
15313: in Lupus, triple, $A B$ : binary, $P=227.8 \mathrm{y}$, orbit almost directly edge-on, rho is rapidly increasing. C is orbiting around $A B, P=1258$ y ?, few data. See fig. 3.
15351: gamma Lupi, binary, $P=190 y$, orbit highly inclined, but reasonably well documented. See fig. 3.
15536: in Scorpius, PA and rho decreasing.
15557: in Scorpius, binary, P = 158 y , two orbits calculated by Scardia [6], own measure seems to better fit to the first one.
15569: xi Lupi, relfix, "splendid".
16035: jota ${ }^{1}$ Normae, triple, all cpm, AB binary, $\mathrm{P}=$ 26.9 y, PA and rho rapidly decreasing, AB-C: few data, PA decreasing. See fig 3.
16038: in Lupus, "neglected", although deemed relfix by Burnham, PA and rho are slowly decreasing.
16044: xi Scorpii, interesting triple, $A B$ : binary, $P=45.8$ $y$, many speckle data. Own measure fits well to both ephemeris and literature data. $\mathrm{AC}: \mathrm{P}=$ ? y , only small portion of orbit covered. Residuals refer to the ephemeris. PA and rho data exhibit large scatter, possibly due to confusion as to which to refer, A or AB. See fig. 9.
16120: nu Scorpii, "double-double", but no orbits determined, rho(AB) slowly increasing, PA(CD) slowly increasing.
16294: alpha Scorpii, "Antares", binary, preliminary orbit, $\mathrm{P}=1218 \mathrm{y}$, only few recent data, own measure close to ephemeris, although difficult because of large difference of brightness of the components.
16425: in Scorpius, binary, "premature orbit", own measure close to ephemeris.
17104: eta Ophiuchi, binary, $P=88 \mathrm{y}$, many speckle data with small scatter. See fig. 3 .
17153: also known as 36 Ophiuchi, binary, $\mathrm{P}=550$ y (?),"premature orbit".
17190: in Scorpius, binary, $\mathrm{P}=42.1 \mathrm{y}, \mathrm{PA}$ and rho rapidly decreasing.
17443: in Apus, binary, $P=101$ y, few data, PA decreasing, rho increasing.
18068: in Corona Australis, binary, $\mathrm{P}=191 \mathrm{y}$, own measures deviate from ephemeris, in accordancewith the trend of speckle data.

## Double Star Measurements at the Southern Sky with a 50 cm Reflector ...

#### Abstract

(Continued from page 81) Catalog of Orbits of Visual Binary Stars [6]. Data available up to December 2014 are taken into account, as of writing this article. In several cases, larger deviations were found, which often agree with trends of literature data. These will be discussed in more detail below. In other cases, literature data are so scarce and/or exhibit so large a scatter that no reasonable residuals can be given.

Systems used for calibration of the image scale were carefully selected. In Table 1, these are marked with shaded lines. Criterion was a well documented history of literature data, i. e. many data with small scatter, generally from the speckle catalog [5], such that extrapolation to the current date was unambiguous. Statistical analysis with 16 pairs resulted in a calibration factor of 0.0967 arcsec/pixel (with Barlow) with an error margin of $+/-0.3$ percent. Maximum error margins for separation measurements are expected to be of the order of $+/-0.02$ arcsec for the range of relatively small separations considered here.

Generally, residuals were calculated as differences against extrapolated literature data, mainly from the speckle catalog, and for binaries against ephemeris data [6]. In some cases, no reasonable residuals could be given, because of too few data and/or too large a scatter. Some systems exhibit significant deviations which are discussed in the notes or below. Residuals of PA and rho values are plotted versus the measured separation in Figures 1 and 2, respectively.

As can be seen in Figure 1, several residuals are greater than the error limits. As they are usually calculated with respect to the current ephemeris, deviations may indicate that this should sooner or later be revised. In fact, in many cases, residuals against the trend of recent measurements are found much smaller. Examples are shown in Figures 4 and $6-8$ below.

The error margins of measurements of the position angle are expected to be of the order of about $+/-0.2$ degrees for large separations, but to increase toward small separations, and can reach several degrees for very close pairs. The reason is the fixed resolution in the images. In fact, this is apparent in the plot in Fig. 2. However, a number of pairs seem to stand out more than this, in particular binaries with not well known orbits.

Some images of double and multiple systems are presented in the following figures. Fig. 3 is a selection of close binaries with sub-arcsec separations.

## Concluding remarks

For many of the doubles investigated here there are only few data found in the literature, and often with

Figure 1. Plot of the residuals of rho versus rho. Semi-logarithmic scale. Pairs used for calibration are marked with superposed open circles. Some systems with large deviations are marked with their names. Symbols with squares denote binaries with significant deviations from ephemeris data. See also notes.

Figure 2. Plot of the residuals of the P.A. versus rho. Semilogarithmic scale. Pairs used for calibration of the image scale are marked with superposed open rhombs. Some systems with large deviations are marked with their names. See also notes.

Figure 3. A selection of close binaries. North is down, and east is right, as in all other star images. See also notes 16035, 15313, 10373, 14587, 12036, 08331, 17104, 08321, 15351, 10062, respectively.

Fig. 4: The orbit of BU 205 AB in Pyxis (WDS 08331-2436). Adopted from reference [6]. Recent speckle data (blue), as well as my own measurement (purple) tend to deviate from the ephemeris. See Fig. 3 and note 08331.

Figure 5a: (Top) The binary $R$ 207/beta Muscae (WDS 12463-6807). Composite of two imaging series recorded on different dates. See also note 12463.
Figure 5b: (Bottom) The orbit of beta Muscae. Adopted from reference [6]. Positions measured in 2012 and 2014 (purple) are on or close to the orbit, but the ephemeris for the respective dates systematically deviate, as indicated. Blue symbols indicate recent speckle data. See also note 12463.

## Double Star Measurements at the Southern Sky with a 50 cm Reflector ...

Figure 6. The orbit of COP 1 (WDS 09307-4028, $\psi$ Vel). Adopted from reference [6]. The measured position (purple) deviates from the orbit, but follows the trend of recent speckle data (blue). See also note 09307.

Figure 8a. (Top) Plot of the position angle versus date of the binary of BU 208 AB in Pyxis (WDS 08391-2240). Open squares indicate speckle data [5], the circle with cross is my measurement of 2014. The solid line is the ephemeris (Hei1990c).
Figure 8b. (Bottom) Plot of the separation rho of BU 208 AB versus date. The meaning of the symbols is as above. Deviations from the ephemeris are clearly greater than the error margins of the measurements.

Figure 7a. (Top) Plot of the position angle versus date of the binary of HWE 28 AB in Centaurus (WDS 13535-3540). Open squares are speckle data [5], circles with crosses are own measurements of 2012 and 2014. The solid line is the ephemeris (Lin1998a).
Figure 7b. (Bottom) Plot of the separation $\rho$ of HWE $28 A B$ versus date. The meaning of the symbols is as in Fig. 7a. Deviations from the ephemeris are clearly greater than the error margins of the measurements.

## Double Star Measurements at the Southern Sky with a 50 cm Reflector ...

Figure 9. The triple xi Scorpii (STF 1998, WDS 160441122). The period of binary $A B$ is about 46 years, while the orbit of $C$ around $A B$ is still not well known. See note 16044.

## (Continued from page 87)

large scatter, although most systems are fairly bright, and easily accessible. The accuracy of my own measurements is checked by comparing with mainly speckle data of systems, which have frequently been measured. Generally, the scatter is of comparable magnitude. As a result of this work, several double star systems were found, which should more often be measured, in order to improve the knowledge about their status, or of their orbits, respectively. In particular, the following systems seem to be interesting:

| WDS Ident. | Name |
| :--- | :--- |
| $08331-2436$ | BU 205 Pyx |
| $08391-2240$ | BU 208 Pyx |

#### Abstract

The video drift method of measuring double stars is a quick and efficient way to obtain position angle and separation measurements. With ordinary video cameras magnitude +12 and deeper double star systems often prove difficult or even impossible to measure without using an image intensifier. A simple modification to the video drift method and corresponding VidPro analysis program now makes reaching magnitude +16 a reality for modest amateur equipment.

## Introduction

In our previous reports using the video drift method (Nugent and Iverson, 2011-2015), we have reported position angle and separation measurements obtained with our respective 14 -inch ( 35 cm ) Meade LX-200 Schmidt-Cassegrain telescopes and other, smaller aperture, telescopes. Author Nugent, using a non integrating Watec 902 H 2 Ultimate video camera fitted with a Collins $\mathrm{I}^{3}$ image intensifier, has measured double stars down to magnitude +15.6 (Nugent and Iverson, 2014). This was accomplished in relatively dry air at his west Texas observatory. Unfortunately the Collins I ${ }^{3}$ image intensifier is no longer being manufactured. Author Iverson measures double stars with a cooled variation of the Astrovid Stella Cam 3 video camera (equivalent to the Watec $120 N+$ camera) which can co-add (stack) video frames within the camera (integration). Coadding 2 frames is the equivalent of doubling the exposure, co-adding 4 frames equates to quadrupling the exposure, and so on. Longer exposure times (with the telescope motor drive on, no drifting) allow reaching fainter stars unattainable with conventional nonintegrating video cameras.

Although the Stella Cam 3 video camera is capable of virtually unlimited user-defined integration periods, hardware-defined integration periods extend up to 8.4 seconds (256 frames). Nugent and Iverson (2012) suggested that integration periods longer than 0.198 seconds (using a Stella Cam EX camera) are impractical with the original video drift method. As the integration time increases, the stars drift in increasingly longer jumps which eventually lead to smearing/streaking of the star images, making them unsuitable for measurement. The freeware program Limovie (Miyashita, 2006), used to measure the stars' ( $x, y$ ) position in each video frame, has a difficult time following the longer jumps. When the program cannot keep up it begins to report inaccurate $(x, y)$ coordinate positions and then it eventually loses the ability to track the stars. Due to this limitation and the humid, unstable air over his east Texas observatory, author Iverson has been unable to routinely measure doubles fainter than +12 magnitude.

While investigating the Reduc double star analysis program (Losse, 2011) and the combined Reduc/VidPro methodology used by Wasson (2014), it was realized that a few simple changes to the video drift method and a corresponding change to the VidPro double star anal-

## Reaching Magnitude +16 with the Modified Video Drift Method

ysis program would significantly increase the depth at which ordinary integrating cameras could measure double stars. These changes include (1) recording the double star at an integration level long enough to allow dim components to be easily seen while the telescope mount is tracking and (2) recording several drifts (no tracking) of a bright nearby star at the same declination to determine the scale factor and drift angle.

## Methodology

In this study we used our respective equatorial mounted 14-inch ( 35 cm ) Schmidt-Cassegrain telescopes and video recording equipment used in our previous papers (Nugent and Iverson, 2011-2015). At the beginning of an observing session, the video camera's chip was adjusted parallel to the approximate true eastwest direction by trial and error rotation of the camera and slewing the telescope. Once aligned, the camera alignment was not changed. The VidPro program compensates for any remaining offset from true east-west. Data was only recorded when the target double star was within one hour of the meridian.

The modified video drift method records video when the telescope is tracking the double star (motor drive on) and when the double star is allowed to drift (motor drive off) across the field of view (FOV). The procedure for recording the necessary video is as follows:

1) Locate the target double star and center it in the video camera's FOV.
2) Choose a camera integration level and gain setting where the secondary star is visible but not saturated. Saturating the primary star is usually unavoidable, but this is not a problem as long as the secondary star doesn't merge with the primary.
3) With the telescope motor drive on, record up to 2.5 minutes of video. The stars may move slightly depending on the telescope balance, the telescope mounts ability to track the night sky, and/or accuracy of the polar alignment. This slight movement does not affect the results. Stop the recording.
4) Adjust the integration time to less than 0.132 seconds. Slew the telescope over to the nearest bright star that closely matches the target's declination (see below). If the primary star is visible then use it.
5) Resume recording and position this star at the eastern edge of the FOV. Turn the telescope motor drive off and allow this star to drift across the entire FOV. Repeat this east to west drift at least 3 or 4 times on this same recording. Now stop recording.

By recording a bright star drifting across the FOV, the video drift method and modified video drift method avoid using calibration (also known as reference or
standard) doubles that some investigators rely on. Calibration doubles are believed to have stable position angle and separations over long periods, thus they provide a reference coordinate system frame for making new position angle and separation measurements for new targets. If the calibration double position angles and separations have not been updated or have significant errors, then these errors will propagate to the new targets being measured. The modified video drift method described here is completely self-calibrating thus no calibration/reference doubles are needed.

## Measurement and Reduction

Once the video is obtained, it's analyzed in two stages. First, the video drifts are analyzed using the freeware programs Limovie and VidPro as previously described (Nugent and Iverson, 2011-2015) with one exception. It is important that both Limovie aperture rings are placed on the drifting star. Since only a single star is used during these drift videos, the VidPro program position angle and separation output cells will show meaningless results. This is not an issue since at this stage we are only interested in calculating the scale factor and camera offset from east to west (drift angle). The averaged result for both quantities will be manually entered into VidPro again during the second step of the reduction.

The second step uses Limovie and VidPro again but this time to reduce the tracking video file. Limovie's aperture rings are placed over the primary and secondary stars. Recall the target double star was not drifting, so the aperture rings will remain essentially stationary (see step 3 above). Because the stars are not drifting across the FOV, VidPro cannot calculate the scale factor or drift angle in this situation. The previously determined scale factor and drift angle from the first step are manually inserted into a modified version of VidPro. As before, Limovie creates a CSV file of $(x, y)$ coordinates for the centroid of each star covered by an aperture ring for each video frame. The CSV file size should be limited to less than 5000 frames or about 2.5 minutes of video. This file is also manually copied into VidPro. When VidPro has all 3 inputs (scale factor, drift angle, and the CSV file), it automatically calculates the position angle and separation along with standard deviations.

The acquisition of the videos using this method takes a bit longer than the original drift method due to the extra time needed to make the tracking video. The level of integration used will significantly influence the amount of tracking data recorded. This is because as integration time increases, fewer new images are available in a given time interval. A camera integrating at

## Reaching Magnitude +16 with the Modified Video Drift Method

sixteen frames outputs a new image approximately every 0.5 second at the NTSC video frame rate. At 128 frames, a new image will be output approximately every 4.2 seconds. The duplicate images do not affect the final result.

In order to prove that there is no significant difference in the results obtained from the conventional VidPro procedures and the modified VidPro procedures, 20 well studied double star systems were selected. Both the primary and secondary star needed to be bright enough to allow drift scanning with either no integration or, if used, then less than 0.132 seconds of integration. Each system was first processed using the traditional video drift method (Nugent and Iverson, 2011). The scale factor and drift angle measurements obtained were then averaged for each double star. Next, each double star was reprocessed using the modified video drift method (steps 1-5 above). The averaged scale factor and drift angle measurements obtained from the traditional analysis were inserted into a modified version of the VidPro designed for use with tracking data.

Ordinary drift scans are essential for VidPro to determine the scale factor and the offset of the camera's video chip from the true east west direction. If a replacement star is used then its declination should be close to the primary star's declination. From Equation 1, below, the cosine of the declination is used in determining the scale factor (Nugent and Iverson, 2011).

$$
\begin{equation*}
\text { scalefactor }=\frac{(\text { driftime }) 15.041068 \cos (\text { dec })}{\sqrt{\left(x_{B}-x_{E}\right)^{2}+\left(y_{B}-y_{E}\right)^{2}}} \tag{1}
\end{equation*}
$$

$x_{B}, y_{B}, x_{E}, y_{E}$ are the beginning and endpoints of the drift, and "dec" is the declination of the primary star or its substitute. Drifttime, in seconds, is defined by the number of frames ( $x, y$ pairs) divided by the camera frame rate. The National Television Standards Committee (NTSC) frame rate is 29.97 frames per second which we round to 30 for convenience.

Reaching fainter double stars with a common integrating video camera is significantly enhanced by using the AviSynth "Level" filter (http://avisynth.nl/ index.php/Levels). It is a one line addition to the AviSynth script (Appendix I) used by Limovie to open the video file. This filter can be used to adjust the brightness, contrast, and gamma of the video clip (Appendix II).

In cases where observations were made over multiple nights or more than one observation was obtained in a single night, the position angle and separation values
were merged using weighted averaging (Nugent and Iverson, 2013). The scale factor and drift angle measurements from multiple drifts were merged as a simple average. All references to stellar magnitudes have been copied from the online WDS summary catalogue.

Table 3 was compiled using the online WDS summary catalogue. It is intended to be only a rough estimate of the total number of double stars visible from the southern United States over the course of a year. The stars included covered a region of the night sky between $90^{\circ}$ north and $-30^{\circ}$ south declination. Any entry in the WDS catalogue lacking a companion star magnitude was not considered. Double stars with a separation less than 5 arc seconds are probably not measurable by the modified video drift method and have been excluded from the table. Most of the southern hemisphere double stars were also excluded from consideration. Percentages were calculated based on a total of 59,590 double stars visible over the course of a year.

## Results

As an initial test of the modified VidPro method, a number of doubles were picked at random from the doubles measured as part of our ongoing double star measurement program. The results from both the modified video drift method (tracking) and original video drifting method for these double stars are given in Table 1. The column titled $P A^{\circ}$ tracking-drifting presents the difference between the position angle results obtained by the two methods. The difference in position angle did not deviate by more than 0.1 degrees over the 20 examples. This is insignificant considering the online WDS summary catalogue gives the position angle to the nearest whole degree. The measured separations also varied by an insignificant amount. For the 20 doubles investigated, the separation did not vary by more than 0.04 arc seconds. Again, the WDS summary catalogue reports separation to the nearest tenth of an arc second. The WDS observational data base includes the known measurements for a double star. It typically reports precisions up to 2 decimal places for the position angle and 3 decimal places for the separation. Entries in this data base just mirror the precision reported by other authors in the literature using a variety of methods.

The standard deviations from the tracking data analysis have been included in Table 1. The standard deviations from the drift analysis are not presented, but they are similar to the values reported in our previous papers.

The next step was to determine the faintest double star that could be measured reliably. Table 2 reports position angle and separation measurements obtained

for 22 doubles where the companion star is too dim or both the primary and companion star are too dim to be measured by the original video drift method. Three of these doubles were observed on multiple nights. The faintest double measured ( $01325+1417$ LDS 1102) has a primary /secondary magnitude of $+11.1 /+16.9$. Since measurements have only been made in the relatively humid, unstable air of east Texas, it is reasonable to expect that even fainter doubles can be measured in a dryer environment with better seeing.

Only 3 of the double stars studied were measured within in the last 5 years and most were measured 15 years ago or longer. Position angle and separation measurements obtained using the modified video drift method (Table 2) in general varied very little from their last historical measurements. In only 4 instances did the position angle change by more than one degree.

The average change was 0.66 degrees. Only one double star ( $01325+1417$ LDS 1102) showed a significant change ( 3.1 degrees). Inspection of the WDS historical data base suggested that this was not unreasonable given the high proper motions of the components. All 22 double stars studied showed very little change in separation from their historical measurements. The maximum change was 0.9 arc seconds while the average change was 0.30 arc seconds. The USNO CCD Astrographic Catalogue project (Hartkopf, W., et al., 2013) derived position angle and separation measurements from the UCAC4 catalogue for 20 of the 22 doubles in Table 2. Inspection of the WDS historical database revealed that in all but 5 cases the most recent measurement was derived from either the 2 MASS catalogue (4 doubles) or the UCAC4 catalogue ( 13 doubles). The close agreement with the UCAC4 measurements sug-

gest the modified video drift method is a useful method for studying faint double stars.

As demonstrated previously (Nugent and Iverson, 2015), the value for both the position angle and separation can be considerably in error based on the trend line formed by plotting the previously reported values. Considering the double stars in Table 2, the most frequently observed system has only 7 previous measurements. The majority of the double stars have less than 5 measurements. Graphical trend line analysis is not very meaningful in this situation.

Table 3 illustrates the increased accessibility of potentially measureable doubles that a southern United States observer might have using the modified video drift method. Using the limits established for author Iverson's observatory as an example, on a night with average seeing (magnitude +11 ), it is estimated that about 29 percent of the available double stars could be measured. On a night with good seeing (magnitude +12 ), this number increases to about 46 percent. However, using the modified video drift method, over 87 percent of the double star systems listed in the WDS

## Reaching Magnitude +16 with the Modified Video Drift Method

Table 3. The estimated number, by magnitude, and the relative percentage of double stars from $90^{\circ}$ north down to $-30^{\circ}$ south declination. This estimate was compiled using the WDS online summary catalogue. See text for an explanation.

| Magnitude | Number of Double <br> Stars < magnitude | Percent of total |
| :---: | :---: | :---: |
| 18.99 | 57225 | 96.0 |
| 17.99 | 54917 | 92.2 |
| 16.99 | 52248 | 87.7 |
| 15.99 | 48727 | 81.8 |
| 14.99 | 43590 | 73.1 |
| 13.99 | 36997 | 62.1 |
| 12.99 | 27582 | 46.3 |
| 11.99 | 17017 | 28.6 |
| 10.99 | 8495 | 14.3 |
| 9.99 | 3580 | 6.0 |

catalog should be within reach. Considerations such as locating the double star at its published coordinates, camera sensitivity to a star's spectral type, and the very slow drift rates at high declinations will limit the actual number of double stars that can be studied with a video camera.

## Conclusions

We have demonstrated that with a 14 -inch telescope, the position angle and separation of double stars down to at least magnitude +16 can be easily measured using the modified video drift method. It is a reasonable assumption that smaller telescopes might see a 3-4 magnitude gain and a corresponding increase in the number of double star systems that can be reached. Both the video drift method and modified video drift method are fast and efficient tools. Traditional CCD cameras which are often very expensive are no longer the only tool capable of measuring dim double star systems. With an integrating video camera, the time involved to collect and analyze the data can be a bit more involved, especially when working at fainter magnitudes. Unfortunately the Stella Cam 3 is now out of production but the principles presented apply equally to other integrating camera brands.

The Image Source line of video cameras may prove useful in double star work. Although they lack the high sensitivity normally found in an astronomical video camera, they are capable of very long exposure times and reduced output frame rates. Additional changes to the modified video drift method may be needed to accommodate these cameras. This type of camera offers two important advantages. First, unlike analog video cameras, the CCD chip uses square pixels, and second, the video signal is digitized inside the camera instead of an external frame grabber. The result is that an aspect correction does not need to be applied to make the recorded image closely match the night sky (Nugent and Iverson, 2014).

## Acknowledgements

This research makes use of the Washington Double Star Catalog maintained at the US Naval Observatory.

## Appendix I

The AviSynth script is used to define the aspect ratio and set the image brightness. See Nugent and Iverson (2015) for an explanation of why the aspect ratio needs to be adjusted to fit the observed night sky for each system.

```
##########################################################
    AviSyth script used by Limovie to open a video file.
##########################################################
ClipMain = ("insert the video file path")
DirectShowSource(ClipMain)
LanczosResize(640,480) #sets the image size used by
                                    #Limovie to 640x480. Adjust this
                                    #value to match the observed sky.
Noise =25 #below this pixel value will be pure black
            #(the noise floor)
IH = 60 #above this pixel value will be pure white
Levels(Noise,1,IH,0,255-Noise, coring=false)

\section*{Appendix II}

The AviSynth "Level" filter is used to adjust the brightness, contrast and gamma of the video clip. See the web page: http://avisynth.nl/index.php/Levels for a complete description.

The AviSynth script file syntax is:
\[
\text { Levels }\left(I_{L}, G, \quad I_{H}, O_{L}, O_{H}, \text { coring }\right)
\]
\(I_{L}\) is the input pixel value that will be set to black and \(I_{H}\) is the input pixel value that will be set to white.

\section*{Reaching Magnitude +16 with the Modified Video Drift Method}

Gamma ( \(G\) ) controls the degree of nonlinearity in the conversion and should be set to 1 for black and white cameras. Making gamma less than 1 will brighten dim stars but it also has the negative effect of increasing the background noise. \(O_{L}\) is the output pixel value that will be set to black and \(O_{H}\) is the output pixel value that will be set to white. Increasing the input-low parameter \(\left(I_{L}\right)\) effectively raises the noise floor and increases contrast. This reduces the amount of noise seen in the Limovie 3D window. Settings up to 30 were common in our analysis. The input-high parameter \(\left(I_{H}\right)\) essentially acts as an inverse gain control. As the value decreases from 255, fainter star images become brighter and therefore easier for Limovie to follow. Settings as low as 50 were used. Changing the output pixel settings reduces the dynamic gray scale range of the image and should be avoided.

Measuring Double Stars with Position Circle and Filar Micrometer Screw: Report \#2
}

\author{
Robert Korn \\ D-Gailenberg, robertjkorn@aol.com
}

\begin{abstract}
I present a list of 54 binaries observed in late 2012. Some remarks on changes against recently measured pairs are given. Also a short discussion about causes and consequences of diverging results obtained.
\end{abstract}

In JDSO Vol. 10 n .3 [1] I presented the method and equipment which I have been using for more than 7 years to measure separation and position angle of binaries.

Here are a further 54 double stars, selected from Washington Double Star Catalog (WDS) and observed and measured in late 2012. The measurements are given in Table 1. The criteria for my choices, just like the equipment and the method, have not been changed and are subject to two factors. The first factor is the limits given by the equipment: pairs with a separation of more than 10 " and a magnitude brighter than 9 . Second, I was looking for objects that showed significant changes in rho and/or theta in the past.

The evaluation of the following list and comparison of the results obtained, against the published measures from other observers in the WDS, gave occasion to investigate whether the divergences found showed some systematic scheme. Therefore I have attempted a graphic evaluation (Figure 1) to show the portion of diverging results over the 13 observing sessions that contributed to the list reported.

Two facts are quite significant. First, most divergences concern the distances, while angle measures are less affected. Second, the later the time of year, the more the quota of divergences increases.

So, I investigated further in the rho-measures; Figure 2 shows the ratio between consistent and diverging rho-measures over the distances, these split in 5 categories of 50 " steps.

Figure 2 shows very clearly that the portion of

Figure 1: Quota of diverging measures in rho and theta over 13 sessions reported.

Figure 2: Ratio between consistent to deviating measures in rho over separation.

\section*{Measuring Double Stars with Position Circle and Filar Micrometer Screw: Report \#2}

Figure 3. Dependence between separation and quota diverging measures of rho.
diverging results increases as distance grows. Figure 3 shows the percent of "divergers" and more clearly shows the connection.

Taking into account all these considerations, I came to the conclusion that the reason for the discrepancies in separation measurements is not a subjective one, but has its cause in the action of the micrometer screw. With typical low harvest and winter-season temperatures here on the mountain-sides, the mechanics become slow reacting, almost as if they have to "go a longer way". In my opinion, decreasing viscosity of lubrication plays a major role in this. This corresponds also with the fact that the deviations manifest in most cases in lower results than to be expected. I will keep an eye on this in the future.

As concerns the qualitative aspect of the issue discussed, I must say that the typical difference between my results and the presumably correct values ranges in general around 2 ". With respect to the fact that the deviations are to be found mostly in the measures of distances \(>150\) ", one must consider that these discrepancies give an erroneous ratio of almost \(2 \%\). This makes
the results obtained usable, but one should consider the fact. Furthermore, it seems remarkable that the relative results in most cases are reported if they adhere to the reported trend; results that go against the reported trend are hard to find.

Some words on ENG11 at 03h07.7+36 \({ }^{\circ} 37\) : I observed this pair October 25, 2012 and found it with a separation of \(132.5 "(\sigma=0.9 ")\) and position angle \(260^{\circ}\). The latter diverged from the WDS value by more than \(9^{\circ}\) ! I tended to believe this to be an erroneous measure on my part, because the sigma was negligibly small, and because the other measures that night were quite in the range of given values to be expected. Then, I found in the JDSO an article by R. Nugent and E. Iverson[2] in which their result on ENG11 - obtained with better and more sophisticated methods than my own - was consistent with my PA measure from 2012 and suggests that the entry in the WDS is erroneous.

\section*{Acknowledgements:}

Gianluca Sordiglioni maintains a useful tool with his website: http://stelledoppie.goaction.it, that gives fast and complex information on double stars. Thanks for that!

This project has made use of the Washington Double Star Catalog maintained at the U.S. Naval Observatory.

\title{
Double Star Observations with a 150mm Refractor in 2014
}

\author{
Marc Oliver Maiwald \\ Witten, Germany \\ oliver-maiwald@web.de
}

\begin{abstract}
In the following article, 166 observations of 84 doubles made with a 150 mm refractor in 2014 are presented. Residuals were calculated for selected pairs.
\end{abstract}

For all observations in 2014, a 150 mm folded refractor with filter 11 (yellow - green) was used. Cameras used were the Imaging Source DMK 21 and the Phillips SPC 900 NC ( NC in Table 1). As in previous years, teleconverters 1,4 (TK1,4 in Table 1) and 2x (TK2 in Table 1) were used for pairs with smaller separations. Wider pairs were observed at direct focus (f in Table 1). The observing technique was the same as described in Maiwald (2013) and Maiwald (2014).

The image scales with the DMK 21 are:
f: 0.384 a.s. per pixel
TK 1.4: 0.297322 a.s. per pixel
TK 2: 0.19876 a.s. per pixel
For the SPC 900 NC with TK2, the image scale was determined to be 0.2091 a.s. per pixel.

For some of the measured pairs, weighted averages were calculated and compared with the ephemeris. Calculation was done with Binary Star Calculator (Workman, 2013) using data from the "Sixth Catalog of Orbits of Visual Binary Stars". The residuals are listed in Table 2.

As exemplified by the measurements of STF 73, STF 1196 AB, and STF 1338 (see remarks 1, 4, and 5 to Table 2 and Maiwald, 2014, p. 191), the error in \(\theta\) for small distances can be rather large. A detailed discussion of the errors in double star measurements with Reduc can be found in Napier-Munn and Jenkinson (2014).

\section*{Acknowledgements}

This paper made extensive use of the Washington Double Star Catalog and the Sixth Catalog of Orbits of Visual Binary Stars, both maintained at the U.S. Naval Observatory. Noncommercial software used was: Binary Star Calculator by Brian Workman; Reduc 3.88 by Florent Losse, Registax 4 by Cor Berrevoets and SharpCap by Robin Glover.

\section*{Table Notes.}
1. The large variations in \(\Delta \theta\) show the difficulties in measuring \(\theta\) for small separations. See Table 3.
2. Residuals for 2009.186 (Courtot, 2010, p.7): \(\Delta \theta-0,8\) and \(\Delta \rho-0,12\) and for 2008.08 (Alzner, 2008, p. 12): \(\Delta \theta-0.7\) and \(\Delta \rho-0.09\).
3. Argyle (2013, p. 3) \(\Delta \theta+4.3\) and \(\Delta \rho+0.03\) for 2012.216; Argyle (2008, p. 5) \(\Delta \theta+3.1\) and \(\Delta \rho+0.01\) for 2006.244; Courtot ( \(2010, \mathrm{p} .7) \Delta \theta+1.6\) and \(\Delta \rho+0.04\) for 2009.21 .
4. Measurements from 2010 to 2012 were published in Maiwald (2013) and for 2013 in Maiwald (2014). The great variation in \(\Delta \theta\) shows that the separation of the star is rather small for my telescope and location. See Table 4.
5. Residuals for my own measurements from 2010.3 to 2013.2 ( \(\Delta \theta\) all negative) can be found in (Maiwald, 2014, p. 191). (Argyle, 2014, p. 4): \(\Delta \theta-3.0\) and \(\Delta \rho+0.09\) for 2013.345 .
6. In (Maiwald, 2014, p.190f.) \(\Delta \theta 6.3\) for 2013.5 was reported.
7. Data for 2012 from Maiwald (2013, p. 193), for 2013 from Maiwald (2014, p. 190). Argyle (2013, p. 4): \(\Delta \theta+4.4\) and \(\Delta \rho+0.07\) for 2012.683. See Table 5.
8. Star is known for deviations from ephemeris. Residuals from 2010.6 to 2013.8 in Maiwald (2014, p. 191). Argyle (2014): \(\Delta \theta-3.4\) and \(\Delta \rho+0.18\) for 2013.538.
9. Residuals from 2010.8 to 2013.8 in Maiwald (2014, p. 191). Argyle (2014, p. 4): \(\Delta \theta-2.4\) and \(\Delta \rho+0.26\) for 2013.864 for the newer orbit.

\title{
Searching for New Double Stars with a Computer
}

\author{
T. V. Bryant III \\ Little Tycho Observatory \\ 703 McNeill Road, Silver Spring, Md 20910 \\ rkk_529@hotmail.com \\ Reprinted from http://mainsequence.org/html/wds/newPairs/FindingUnlistedDoubleStars.html
}

\begin{abstract}
The advent of computers with large amounts of RAM memory and fast processors, as well as easy internet access to large online astronomical databases, has made computer searches based on astrometric data practicable for most researchers. This paper describes one such search that has uncovered hitherto unrecognized double stars.
\end{abstract}

\section*{Introduction}

Recently, four previously unlisted double stars were added to the Washington Double Star Catalog (WDS) \({ }^{1}\) as a result of the process to be described in this article. They are shown in Table 1.

These pairs were located by a computer search of the fourth USNO CCD Astrographic Catalog \({ }^{2}\) (UCAC4). Using the CD provided by the United States Naval Observatory \({ }^{3}\) (USNO), a suite of programs written in Perl and C was used to search the UCAC4 for candidate binary pairs that were not in the WDS.

Pairs that passed this test were then placed into a list for manual verification, using the Aladin \({ }^{4}\) tool.

Using Aladin, the candidate pair was manually examined. Pairs that seemed to be associated with nearby clusters were eliminated, as were pairs enmeshed in nebulosity to the point that they could not be accurately measured with Aladin. Pairs that passed these tests were then measured for position angle and separation,
using Aladin's UCAC4 template on the DSS plate, and placed in a final list of candidates.

The four entries from this final list of pairs were chosen based on their visibility in the summer sky from \(39^{\circ}\) north latitude, brightness, separation, and a large proper motion. These stars were observed from the Little Tycho Observatory, and then submitted to William Hartkopf \({ }^{5}\) of the USNO.

\section*{Search for Unlisted Double Stars from the UCAC4 Data}

The instructions given below have been shown to work in a Linux development environment. While they can be replicated in other environments, e.g, an Apple Mac, or the Cygwin environment on a Windows PC, they have not been tested in these environments.

\section*{Obtain a copy of the UCAC4 data.}

You'll need to send an email to brenda.hicks@navy.mil with "UCAC4" in subject and your full name and postal mailing address in the body of

Table 1: Double stars recently found by computer search and added to the WDS.
\begin{tabular}{|c|c|c|c|}
\hline RA + Dec: J2000 & UCAC4 Designation & Primary mv & Secondary mv \\
\hline \(16: 39: 17.31+26: 27: 28.92\) & \(583-54539\) & 10.15 & 11.325 \\
\hline \(17: 16: 01.38+25: 16: 05.87\) & \(577-56486\) & 10.652 & 12.202 \\
\hline \(19: 50: 41.95+20: 18: 29.21\) & \(552-99070\) & 9.22 & 10.5 \\
\hline \(20: 43: 31.93+52: 16: 35.77\) & \(712-76210\) & 9.51 & 10.96 \\
\hline
\end{tabular}

\section*{Searching for New Double Stars with a Computer}
your e-mail.
A CD of the data will be sent to your address. When it arrives, mount the \(\mathrm{CD}(\mathrm{s})\) in your computer's CD drive and download the 900 UCAC4 declination zones to a directory on your computer.

\section*{Obtain a copy of the WDS data.}

On a computer equipped with the wget program and connected to the internet, the following command should do the trick:
```

    cd /DirectoryWhereYouWantToStoreTheData/
    wget -r -O wdsData http://ad.usno.navy.mil/wds/
    Webtextfiles/wdsweb_summ.txt

```

The file wdsData should now be downloaded to your current working directory:

DirectoryWhereYouWantToStoreTheData.

\section*{Getting the code}

It is assumed that the reader is somewhat familiar with programming and the C and Perl languages in particular in this section.

Code can be obtained from GitHub, or the author's web site, http://www.mainsequence.org/html/wds/ newPairs.

In downloading code from the author's web site, you can list the program by left-clicking on the link below, and download it by right-clicking (Ctl-click on a Mac)

The WDS is listed in order of its positional Ids, a low precision J2000 coordinate designation, as opposed to a pair's precise coordinates. A short Perl program has been written to extract the precise coordinates from the WDS which can be downloaded from
```

getWDS_PrecisionCoordinates.pl

```

The program is run from the directory containing a recent copy of the WDS catalog.

The resultant file, WDS.pre, is then sorted using the unix sort command:
```

sort -n WDS.pre > wdsPrecisionCoordinates

```

As the UCAC4, as of this writing, consists of 113,780,093 stars, it was not efficient to search the entire declination range of the catalog for each of the candidates. MkUCAC4_Regions.c reads the catalog and then splits it into files, each of which covers approximately a square degree of sky. Stars that border (within 30") a square degree are also included in the file. In this way, when a candidate star is searched for possible companions, only a single square degree need be searched. The program also creates a list of possible primary candidate stars, all brighter than mvC (Default setting for this is \(11000=11.0 \mathrm{mv}\) ) that findUnlistedDoubles.c will use for the search. Click on the link below to download the code.

\section*{mkUCAC4_Regions.c}

Edit the program's holding directory location in lines 65 and 68 to match where you would like its square degree files to be written. The directory used to store the UCAC4 data must also be changed in line 104.

The program can be compiled using this command:
gcc -std=gnu99 -o2 -o mkr -W mkUCAC4_Regions.c -lm
and run using this: mkr

\section*{Find candidate binary pairs not in the WDS from UCAC4 data}

Now that we have the precision coordinates from the WDS and the UCAC4 data for the brighter stars stored in square degree files, we can search for pairs not in the WDS with findUnlistedDoubles.c. Click on the link below.

\section*{findUnlistedDoubles.c}

Many of the search parameters set by both programs can be changed, the programs recompiled, and different results obtained. If a very loose set of parameters is used, many thousands of possible pairs can be generated. More restrictive parameters will result in fewer pairs. Once the user is familiar with editing and compiling the programs, many interesting lists can be generated. Each list takes only about 5 minutes to compile and create on the author's machine. It complies with a command similar to the one given above.

The program's output file is in HTML format. Read it in your browser by opening it as a file. A sample output can be seen at the link listing 1.

The program ships with these default parameters. Their default values are the numbers in parentheses following the parameter's name:
- Only stars brighter than mvC (11000) are considered as primary candidates. Generally, the brighter the star, the more information about it is to be found in the literature, simplifying subsequent study. This can be changed by changing the value of mvC in mkUCAC4_Regions.c.
- Secondary stars must be brighter than mvS (12000) to be considered. This again can be changed by changing mvS in findUnlistedDoubles.c and mkUCAC4_Regions.c. Note that the UCAC4 does not list many stars fainter than 16.0 mv (16000).
- The primary and secondary should be within dMv (1000) of each other. This is a fairly arbitrary restriction, and is used to simply cut down on the number of pairs found.

\section*{Searching for New Double Stars with a Computer}
- XXX (30) is the size of the region of sky that will be searched, in arc seconds. A box of sky twice this distance on a side will be searched for possible companions to a given candidate star. This can be changed by changing XXX in both mkUCAC4_Regions.c and findUnlistedDoubles.c. Note: The programs have only been tested with XXX set to 30 ". Change this at your own risk!
- The minimum separation between the stars should be minSep (10) arc seconds or more. Pairs are manually verified by examining them on DSS plates. A pair of stars with less separation can be very difficult to differentiate from a single star.
- The larger the maximum separation, maxSep (30), the less likely a pair will be physical. Unless XXX is changed, 30 should be the largest separation used.
- The average proper motion of the two stars must be larger than minPM (50) milliarcseconds per year (mas/yr). This will help to eliminate slow moving pairs that are optical.
- The difference between the average proper motion of the candidate pair and their individual proper motions should be less than a given quantity pmR (5). This condition helps to eliminate possible optical pairs, and is defined as the differences between the primary and secondary proper motions. For example, if a pair had an average proper motion of 70 mas/yr but one component was moving north of the average proper motion at \(30 \mathrm{mas} / \mathrm{yr}\), the other south at \(20 \mathrm{mas} / \mathrm{yr}\), the pair would be rejected because of their individually disparate, though large, proper motions.
- There must not be a binary listed by the WDS within XXX arc seconds of the candidate pair. Visual magnitudes were ignored for this condition, as many WDS listings show magnitudes different from the UCAC4 magnitudes.
- The program converts all of its angles to radian measure for calculation, and then back to degrees or hours, minutes, and seconds for output.
- The output coordinates are in a format such that you can easily drag and drop them into DSS display tools such as Aladin, GoogleSky, or WikiSky.
- When a parameter is changed, the changed program must be recompiled before the changes will take effect.
- Directories that hold the UCAC4, WDS, and output data are as found on the author's computer. These will probably need to be changed to fit the user's computer.

\section*{A sample list}

A sample list of possible binary stars not in the WDS is given in Table 2 at the end of this article. Column headers are as follows:
- RA and Dec are the J2000 coordinates of the primary.
- mv and mvb are the visual magnitudes of the primary and secondary, respectively. They are in units of millimagnitudes, that is \(9000=9.0 \mathrm{mv}\).
- mv src and mvb src are the source of the magnitude measurement, APASS (the AAVSO survey) or UCAC4 (the UCAC4 model magnitude).
- \(\rho\) is the separation of the pair, in arc seconds.
- Double Flag is the UCAC4 double flag for the primary.
- Primary and secondary proper motion in both right ascension and declination are given in milliarcseconds per century.
- A and B UCAC4 id give the UCAC4 declination zone and star number in that zone of the primary and secondary, respectively.
- Comments can be edited or added as further study of a pair is done.

Questions, comments, or submissions may be directed to rclark@southalabama.edu or to rmollise@bellsouth.net

The Journal of Double Star Observations (JDSO) publishes articles on any and all aspects of astronomy involving double and binary stars. The JDSO is especially interested in observations made by amateur astronomers. Submitted articles announcing measurements, discoveries, or conclusions about double or binary stars may undergo a peer review. This means that a paper submitted by an amateur astronomer will be reviewed by other amateur astronomers doing similar work.

Not all articles will undergo a peer review. Articles that are of more general interest but that have little new scientific content such as articles generally describing double stars, observing sessions, star parties, etc. will not be refereed.

Submitted manuscripts must be original, unpublished material and written in English. They should contain an abstract and a short description or biography ( 2 or 3 sentences) of the author(s). For more information about format of submitted articles, please see our web site at http://www.jdso.org

Submissions should be made electronically via e-mail to rclark@southalabama.edu or to rmolise@bellsouth.net. Articles should be attached to the email in Microsoft Word, Word Perfect, Open Office, or text format. All images should be in jpg or fits format.

We're on the web!
