#### Abstract

Position angles and separations for 227 multiple star systems are presented using the video drift method. The drift method generates standard $(x, y)$ coordinates for the primary and companion star for each video frame during the drift. Position angle and separation are derived from these coordinates. Systems fainter than $m=+12$ were measured and computed using a variation of the drift method using an integrating video camera. Most doubles had 1,000's of $(x, y)$ pairs a analyzed per system. Several systems lacked measurements since the late 1800's and early 1900's.

## Introduction

In our first paper (Nugent and Iverson, 2011) we described a new video method that computes both the position angle (PA) and separation (Sep) for a double star. A significant advantage of this method is that data collection and subsequent data analysis is almost completely automated with little human interaction. A short video clip of the multiple star system drifting across the field of view is evaluated by the freeware program Limovie (Miyashita, 2006) to capture 100's to 1,000's of ( $x, y$ ) positions (aka "standard coordinates") for each component. Although Limovie was originally written to measure the change in light levels during an occultation, it also produces a table of standard $(x, y)$ coordinates for both components along with their brightness levels for each video frame. VidPro, an Excel program written by co-author Nugent, reads the $(x, y)$ coordinate data and computes the position angle and separation for each video frame. The position angles and separations are then averaged to give a final result.

Each double star drift is self calibrating. The VidPro program computes a unique scale factor, an offset from the east-west direction compared to the camera's pixel array, and standard deviations for both position angle and separation for each drift. The offset of the pixel array alignment of the video camera's chip from the true east-west direction (drift angle) is calcu-
lated using the method of least squares to an accuracy of better than $0.02^{\circ}$.

For systems in which either primary and/or secondary star magnitude exceeded $m=+12$, co-author Iverson used a variation of the drift method employing an integrating video camera (Iverson and Nugent 2015). Author Nugent uses a Collins I ${ }^{3}$ image intensifier with his 14 inch SCT telescope and routinely reaches $m=$ +14 to +15 .

## Methodology

Preference was given to multiple star systems where the WDS lacked measurements for a minimum of $10-15 \mathrm{yr}$ and had less than 10 measurements. This criterion applies to nearly all of the multiple star systems measured at the epoch of their measurement. In some cases where one component of a complex system meets this requirement, all of the other components within the reach of our telescopes were also measured for completeness even though they have been well measured in the past. Twenty-seven doubles had more than 35 measurements. We routinely look at a few well measured doubles to support ongoing efforts to compare the video drift method with other measurement methods. Nineteen systems lacked measurement since 1893-1945. The faintest system measured in Table 2 had primary/secondary magnitudes of $+10.0,+15.0$. One dozen systems had WDS magnitudes in the +14.0

## Double Star Measures Using the Video Drift Method - VI

to +14.8 range.
With some doubles not measured since the late 1800's or early 1900's, significant deviations in PA and Sep were sometimes observed. This is not surprising. These doubles were checked with the interactive Aladin Sky Atlas webpage (from the Centre de Données astronomiques de Strasbourg) to verify that the stars originally observed were identified and re-measured by us. Updated proper motions were taken into account from catalogs from the VizieR database to confirm the observed changes in PA and separation.

Other doubles showed a significant deviation from the WDS summary catalog value. The observational history was obtained from the U.S. Naval Observatory and both the position angle and separation were plotted against the year of observation. In most cases the data conformed to a general trend line. In a few cases the fit was very good and the least squares correlation coefficient was greater than 0.90 . Graphing the data also showed which data points were obviously in error. These were rejected and not included in Table 2. An investigator comparing their new measurement to the latest WDS catalog value, and noting a large difference, might reject their measurement. However the new measurement might be a good one, since the WDS is known to have some values that have large errors, especially when there is just 1 or 2 measurements for a given double star system.

## Calibration

In our previous paper (Nugent and Iverson, 2014), we discussed how to make a one time calibration to set the correct aspect ratio for the hardware configuration used for the recording of the videos. This calibration makes a slight adjustment to the video aspect ratio (width vs. height) to overcome the unavoidable skewing of the image aspect ratio caused by modern digital video recorders. With the one time video size adjustment (done automatically using an AviSynth script when Limovie opens the video file), our video aspect ratios closely matched the sky in the east-west and north-south directions. To confirm this, we measured long term stable doubles with no change in PA, Sep and also used RA, DEC coordinates from the VizieR online star cata-
logs to compute the angular displacement and separation of known stars.

The telescope equipment used and scale factors are summarized in Table 1.

## Acknowledgements

This research makes use of the Washington Double Star Catalog maintained at the US Naval Observatory, the Aladin Sky Atlas Interactive webpage and the VizieR catalog database from the Center de Données Astronomiques in Strasbourg, France.

## Table 2 Notes

All magnitudes were taken from the WDS catalog. All position angle/separation measurements are for the Equator and Equinox of date.

Column titled "No. of ( $x, y$ ) pairs" is the total combined no. of ( $x, y$ ) pairs (video frames) from all drift runs. All video frames were used, none were discarded.

The column "drifts" is the number of separate drifts made. "Nights" is the number of successive nights drift runs were made for that system.

WDS 01304-1903. A single observation in the WDS catalog from 1916 is likely a measurement of a mirror image. WDS $\mathrm{PA}=39^{\circ}$, our measurement is $310.2^{\circ}$. Proper motions for the components are insignificant. WDS reports this double with an "X" code, meaning dubious to its existence. The WDS RA, DEC of the primary (not the secondary) was a match for the system we measured and from the POSS image. See Figure 1.

Figure 1. WDS 01304-1903. POSS image from 15-Sep-1954. North is up, FOV is 8 arc minutes. See Table 2 notes for discussion.

# Wide and Faint Double Star Photometry and Measurement with Online Tools - Test Drive with Landolt Standard Stars and Example with ROE 76 in Perseus 

Wilfried R.A. Knapp<br>Vienna, Austria<br>wilfried.knapp@gmail.com

#### Abstract

Using Landolt standard stars as reference, it is shown that generally available online tools can with moderate efforts deliver reliable photometric results, and with the example of ROE 76 in Perseus it is also shown that measuring of wide double stars is quite possible. By chance ROE 76 also offered the possibility to do some astrometry with online tools.

## Introduction

Old fashioned visual double star observers with session plans containing hops from one double to another often visit faint and wide pairs as humble hops between "more interesting" doubles. It is only a question of time untl it becomes evident that a good number of these objects are listed with questionable magnitudes in the WDS catalog (as is the case in most star catalogs). They are easy to recognize by the missing second digit in precision, indicating a possibly estimated or old measurement.

It is certainly possible to try to do a better estimating job than the discoverer and in this regard it might even be an advantage to be restricted to a smaller amateur telescope to be aware that the components of a specific double have to be much fainter than listed - else one would be able to resolve it in a humble amateur telescope. Some research can then be done in other star catalogs to check if there might be other magnitude information on the pair. Tycho II usually delivers a value for the primary, or a combined magnitude for both components, and USNO or UCAC4 most of the time give a suggested model fit or aperture photometry magnitude for the secondary if the separation is wider than $2^{2 \prime}$. When lucky, APASS provides a precise measurement of the visual magnitude of the secondary (then listed in UCAC4 as Vmag), but this is not as often as desired. The USNO can then be informed about the
latest observation and the data found elsewhere and (if necessary) get a change in the WDS data to the better, but the magnitude still remains an estimate (with the exception of an existing APASS value). It would then be nice to be able to do some photometry with reasonable effort.

Online telescope providers offer different levels of services and at least some deliver a rather professional quality for making images usable for photometry and other measurements. Such images can then be uploaded to the AAVSO online photometry tool $V$ Phot. Prerequisite for using VPhot is a valid TIFF-header, good enough image quality for plate solving, usage of a photometry filter (especially V for visual magnitudes), and a definition of the parameters of the used telescope. Some online telescope providers even offer automatic plate solving and upload to VPhot so these steps can already be included in the imaging session plan.

After some initial experiments one quickly gets the feeling for selecting the suitable exposure time needed for good results with different levels of star brightness and other factors - long enough to get star disks with a good signal to noise ratio (SNR) and short enough to avoid overlapping of the star disks from primary and secondary. Stacking several images with rather short exposure time is also a good idea to get a better image quality, including better SNR.

Now comes the process of defining the sequence. First, select the objects for photometry. Then comes the

## Wide and Faint Double Star Photometry and Measurement with Online Tools - Test Drive ...

critical step to select comparison stars in the field of view. Predefined AAVSO comp stars are rather scarce in some areas; the same goes for AAVSO standard stars. Surprisingly, APASS has no predefined VPhot source for comp stars, but this will hopefully be changed in the near future. SIMBAD might be used to select comp stars but the available catalogs rarely deliver reliable magnitudes for fainter stars.

An alternative is to use UCAC4 objects in the FoV with the given V-mags, assuming that such values are usually from APASS or sources of equivalent quality.

The next step is to select objects of similar quality for check stars to get an impression of how precise the delivered photometry results might be and to define photometry aperture radius and sky annulus. Then, save the sequence, click "Photometry Report", and see what result is obtained. Some adjustments might need to be made when the given measurement error seems too large, the check star indicates a questionable sequence, or some comparison stars seem a bad choice indicated by a red colored background in the target estimate column.

## Test with Landolt Standard Stars

To check the quality of the results of such a procedure, I made an image of a group of stars with Landolt standard stars. The Landolt catalog consists of several hundred faint stars near the celestial equator with "approved" magnitudes used by AAVSO as "official" comp stars for photometry.

I selected the star field around TYC0012-00214-1 (Landolt 92342 = AAVSO comp star \#116) in Cetus and made a single image with a 12 " f/9.3 RC-scope situated in Siding Spring, Australia with 15 s exposure time using the V filter. Due to the rather low altitude of $\sim 32^{\circ}$ the air mass was a rather high 1.888 , but the image showed as planned four Landolt stars in good quality (Figure 1).

In the first VPhot run, I selected the two northern stars with given UCAC4 Vmags as targets with three of the Landolt stars $(92342,92250,92348)$ as comp stars and one Landolt star (92335) as a check star. This resulted in the photometry results given in Table 1.

This result shows that without any additional actions, like stacking, we get values well within a small error range. The next step in testing this setup is a change in direction using UCAC4 objects with Vmag values as comp stars and checking the results against the Landolt standard values. This resulted in the photometry results given in Table 2.

Again these results seem of very acceptable quality to me with even the worst result less off than 0.1 mag and this with only two comp stars for three target stars and no actions at all to enhance the results - at least I

Figure 1. Test image with Landolt stars as AAVSO comp stars marked

Table 1: VPhot photometry results with standard comp stars

|  | Name | Vmag | VPhot | Delta |
| :--- | :---: | :---: | :---: | :---: |
| UCAC4 | $455-001259$ | 13.251 | 13.201 | 0.050 |
| UCAC4 | $455-001260$ | 12.805 | 12.855 | 0.050 |
| Landolt 92335 (check) | 12.523 | 12.559 | 0.036 |  |

Table 2: VPhot photometry results with UCAC4 Vmag comp stars

| Name | Vmag | VPhot | Delta |
| :--- | :---: | :--- | :--- |
| Landolt 92250 | 13.178 | 13.088 | 0.090 |
| Landolt 92342 | 11.613 | 11.638 | 0.025 |
| Landolt 92348 <br> Landolt 92335 <br> (check) | 12.109 | 12.110 | 0.001 |

Table 3. WDS values for ROE76

| WDS | Comp | PA | Sep | Mags |
| :---: | :---: | :---: | :---: | :---: |
| $03340+4048$ | AB | 36 | 4.5 | $9.19,10.3$ |
| $03340+4048$ | AC | 156 | 87.4 | $9.19,10.58$ |

think that such photometry results are certainly much better than the best possible estimates.

## Wide and Faint Double Star Photometry and Measurement with Online Tools - Test Drive ...

Figure 2. Image of ROE76

## Example ROE76 in Perseus

ROE 76 is listed in WDS (on January 31, 2015) with the values shown in Table 3 and with precise RA 03:33:55.460 and Dec 40:49:36.498.

I selected this multiple because the magnitude for B is listed in the WDS with only single digit precision and a quick lookup in the UCAC4 catalog indicated missing objects for B and C. On January 17, 2015, at 7:00 PM I took a single image with a 5 s exposure with a 12 " $\mathrm{f} / 8 \mathrm{CDK}$ scope (resolution 0.73 " per pixel) located in Nerpio, Spain with V filter at an altitude of about $67^{\circ}$ and thus an air mass of only 1.024 and got the image shown in Figure 2.

As a slight complication, this scope delivers images with a horizontal and vertical flip plus about a $45^{\circ}$ rotation and there is a glitch in the data transfer between scope and VPhot as the image orientation VPhot indicates it is off by $90^{\circ}$ - this is in this case very important, as a counter check with WDS showing that there is something wrong with the RA+Dec position given in the WDS catalog. The correct orientiation of the image could be easily checked by loading SIMBAD data into the image (Figure 3).

To check against the ROE 76 position data given in WDS, I made a star map based on WDS data (Figure 4). Next, I made a star map for the same field of view with the UCAC4 catalog, shown in Figure 5.

This is a clear hint that there might be something wrong with the WDS position data for ROE76. With the help of Aladin, I looked at the 2MASS image for HD 21961 and found another confirmation that the WDS data is wrong. Assuming RA/Dec coordinates for A and separation and PA for the components as given, this means a mismatch of positions and objects. AC would then be $A B$ with RA and Dec as given and $A B$

## Wide and Faint Double Star Photometry and Measurement with Online Tools - Test Drive ...

Table 4. UCAC4 mags for ROE76 components ( $1=$ Vmag, $2=$ model fit )

| ROE76 | UCAC4 | WDS mag | UCAC4 mag |
| :---: | :---: | :---: | :---: |
| A | $655-016333$ | 9.190 | 9.5001 1) |
| B | $655-016340$ | 10.300 | $10.2381)$ |
| C | $455-001260$ | 10.580 | 11.636 |

would be BC with RA 03:33:58.608 and Dec 40:48:16.848.

Now comes the topic of magnitudes. First, we can check again UCAC4 as we have now a UCAC4 object for each ROE76 component, Table 4.

For the C component, UCAC4 lists no Vmag (confirmed with negative APASS query), so we have to settle with the model fit magnitude estimation (usually more reliable than the aperture photometry value, in this case a rather odd +10.391 ). These values indicate a potential problem with the magnitude for C (and not with $B$, as was the initial idea for this research), so the next step is photometry with VPhot. The image quality may not be perfect as the star disks for $B$ and $C$ are touching (so it might have been better to make several images with shorter exposure time and stack them), but we have to use what we have and it works rather well. We have a good number of UCAC4 comp stars with Vmags available as shown in Table 5. Table 6 gives the results from Vphot.

This result is obviously in a reasonable error range suggested by the values for the check stars and suggests that the WDS mags for A and B are within some error range correct but that C is about 1 mag fainter than listed, as already indicated by the UCAC4 model fit magnitude.

As VPhot offers also a tool for calculating separation and position angle, we can check also these values, with the result shown in Table 7.

Besides the switch of components, these results confirm the WDS values at least for AB with some minor doubts for BC - but we have to consider the lack of precision of the VPhot results depending on image resolution ( $0.73^{\prime \prime}$ per pixel). But as we have now a precise RA/Dec values from UCAC4 we can do precise calculations for separation and PA

Finally, we get the photometry and measurement result for ROE76 shown in Table 8.

## Conclusions

The setup with iTelescope and AAVSO VPhot is already in the simple form with single images quite useful for photo- and astrometry for wide faint double stars especially for the determination of the magnitude

Table 5: Comp stars for ROE 76

| Object | Vmag |
| :---: | :---: |
| UCAC4-654-015822 | 11.929 |
| UCAC4-654-015857 | 10.934 |
| UCAC4-655-016242 | 10.413 |
| UCAC4-655-016292 | 12.323 |

Table 6. Vphot results for ROE 76

| Name | Vmag | VPhot | Delta |
| :---: | :---: | :---: | :---: |
| ROE76A | 9.190 | 9.134 | -0.056 |
| ROE76B | 10.300 | 10.431 | 0.131 |

Table 7: Separation and Position Angle for ROE76 according to VPhot compared to WDS (with switched components)

|  | WDS |  | VPhot |  |
| :---: | :---: | :---: | :---: | :---: |
| Object | Sep | PA | Sep | PA |
| ROE76AB | 87.4 | 156 | 87.3 | 155.9 |
| ROE76BC | 4.4 | 36 | 3.77 | 38.73 |

of rather faint secondaries. There is still room for improvements with stacking and other techniques providing better image and data quality and reducing random errors. It would also be useful to do additional photometry with $B$ filter to be able to calculate the $B-V$ color index indicating the degree of reddish tint, making it more demanding for visual resolution.

# Measurements of Neglected Double Stars: February 2015 Report 

Joseph M. Carro<br>Cuesta College, San Luis Obispo, California

#### Abstract

This article presents measurements of 44 double stars. The stars were selected from the Washington Double Star Catalog published by the United States Naval Observatory. The photographs were taken by remote telescopes. The measurements were done by the author.

## Methodology

Photographs were taken using telescopes operated by the SLOOH observatories, which are part of the Institute of Astrophysics. One of the observatories is located in the Canary Islands near the west coast of Africa. That telescope is located at an elevation of 2,300 meters on the island of Tenerife. The instrument has a focal length of $3,910 \mathrm{~mm}$, an aperture of 356 mm , and is a Celestron unit of Schmidt-Cassegrain design. The other observatory is located near Santiago, Chile. That telescope is the same model as the unit located in the Canary Islands. The methods used to calibrate the instruments of the SLOOH observatories are unknown to this author.

The camera used most frequently was a CCD SBIG 10XME, but some photographs were taken using a CCD SBIG 2000 XM . The photographs were analyzed by the author using the programs CCD Soft v5 and SKY 6 The two programs are products of Software Bisque.

After accumulating the photographs, averages were calculated for the position angles and separations. All of the star patterns were compared with the data from ALADIN (part of the SIMBAD site), or with the SKY X program to insure correctness. After measuring each star and calculating the results, comparisons were made with the published data. The results are listed in the tables, which contain averages of measurements, or, in the case of a single measurement, the actual value. The statistical calculations were rounded to one decimal place in accord with significant figure rules.

## Report

The following information was reported for each star: the WDS code with components, the discoverer code, the constellation, the position angle, the separation, the date of the first observation, and, under measures by the author, the results of other authors. The number of measurements, and the WDS values were taken from the WDS on the first observation date.

The column headings are: Washington Double Star identifier and components, $\mathrm{DC}=$ Discovery Code, $\mathrm{PA}=$ position angle, $\mathrm{SD}=$ standard deviation, $\mathrm{SE}=$ standard error of the mean, $\mathrm{Sep}=$ Separation, Mts $=$ number of measurements, Con = Constellation, and the first observation date.

## Acknowledgements

Grateful appreciation is extended to Russell Genet for his guidance and to Thomas Smith for his support.

This research made use of the SIMBAD database operated at CDS, Strasbourg, France, and the Washington Double Star Catalog maintained by the United States Naval Observatory.

## Measurements of Neglected Double Stars: February 2015 Report

## Notes:

05231+3802 AB: In the article written by Williams, it appears that the reported measurements were from $B$ to $A$, as the values were 268 and 26.2.

05284+3546 AB: Based on the published data, it appears that the C and D components of this group are mislabeled in the article by Williams.

05485-1322 A-BC: Seven measurements were taken over a period of one month, due to the variations in the values. While the average is an acceptable $99.1 \%$ of the published value, the standard deviation is greater than is desired. The separation is $98.2 \%$ of the published value, and the standard deviation is an acceptable $+/-0.7$.

06346+0821 AD: Four photographs of this double star were taken over a period of one month, but this pair was not found in any of the photographs.

07260+1406 AB: Five measurements were made from 17 December 2014 to 19 January 2015. The position angle measurements yielded an average of only 190.7 with a standard deviation of 4.9. The WDS value was 197. The average separation was an acceptable 10.7 versus 11.0 as published in the WDS. More meaurements will be necessary on the AB components. From the photographs I received, the $A F$ and AR components could not be identified.

07578-6048 BC: This pair, with discover code TOB 356 , was present in the photographs, but the closeness made measurements impossible with my equipment.

09045-5620 AB,C: Eight measurements were taken over two months (17 December 21014 to 4 February 2015) with mixed results. The position angle average was 216.0, less than the 225 given in the WDS, a difference of $4 \%$ with a standard deviation of 2.6. The separation was good at 12.9 versus 13.0.

# Photometry and Measurement of Faint and Wide Doubles in Eridanus 

Wilfried R.A. Knapp<br>Vienna, Austria<br>wilfried.knapp@gmail.com<br>Chris Thuemen<br>Pembroke, Ontario, Canada<br>thuemen_cm@yahoo.ca

#### Abstract

Images of several double stars in Eridanus published on the "Double Star Imaging Project" Yahoo Group page suggest magnitude issues compared with the corresponding WDS catalog data per 2014.12. Taking additional images with V-filter enabled photometry for these pairs with confirming results.

## Introduction

Evaluating "Double Star Imaging Project" images made in Eridanus, we found several double star systems displaying, primarily, stellar magnitudes that were noticeably different from what one would expect based on the data listed in the WDS catalog. First conclusions were the following:

- HJ342 AC - WDS 04233-0500. Listed magnitudes of 7.76 \& 12. Image by Stephen McGaughey \& John Pye shows " C " to be much fainter than +12 magnitude. UCAC4 lists +13.279 mag model fit for C, no Vmag.
- HJ 2187 AB - WDS 03233-1121. Listed magnitudes of $7.7 \& 10.4$. Image by Chris Thuemen suggests quite strongly that the secondary is considerably dimmer than the listed magnitude. UCAC4 lists +12.216 Vmag for B and +8.842 Vmag for A , indicating that "A" is also fainter than the WDS data.
- JC 1 AF - WDS 03195-2145. Listed magnitudes of $3.91 \& 12.33$. Image by Chris Thuemen suggests that " F " is brighter than the listed magnitude. UCAC4 lists " F " with +11.809 Vmag.
- ARA 1976 AB - WDS 03351-2309. Listed magnitudes of $9.33 \& 10.6$. Image by Chris Thuemen
suggests the secondary is noticeably dimmer. UCAC4 lists "B" with a +11.310 mag model fit, no Vmag and "A" with +9.534 Vmag, suggesting that "A" might be a tad fainter than the value listed in the WDS.
- BU 401 AC - WDS 03503-0131. Listed magnitudes of $9.33 \& 10.6$. Image by Chris Thuemen strongly suggests that " C " is a good deal dimmer than the WDS data. UCAC4 lists C with +12.838 Vmag.
- HJ 668 AB,C - WDS 03509-0010. Listed magnitudes of $8.49 \& 10.9$. Image by Chris Thuemen tells a very different story from the WDS data and UCAC4 lists "C" with 12.290 mag model fit, no Vmag.
- Struve 463 AB - WDS 03516+0020. Listed magnitudes of $9.3 \& 12.1$. Image by Chris Thuemen suggests the companion to be much brighter than the WDS records. UCAC4 lists "B" with +11.188 mag model fit, no Vmag.

Links to the images referred to above can be found in Table 4 at the end of this article. A summary of WDS 2014.12 data is given in Table 1.

## Photometry and Measurement of Faint and Wide Doubles in Eridanus

## Further Research

To investigate further our initial findings, we concluded that the best approach would be to obtain new images suitable for photometry. These images were taken with an online $510 \mathrm{~mm} \mathrm{f} / 6.8$ CDK telescope having a resolution of 1.1 seconds per pixel and equipped with a V-filter, located in Siding Spring, Australia. Photometry was completed on several additional UCAC4 listed stars within the field of the double star system for the purpose of comparing and checking the new magnitude values against those listed in the UCAC4 catalog. In addition, and by using the formula provided by R. Buchheim (2008), new separation and position angles were calculated for all systems based on the UCAC4 values which are assumed to be the
most precise available coordinates. The new values are included in Table 2 below.

## Additional Results for JC1

It would also have been of interest to check the magnitude of JC1 B because the +9.5 value given in the WDS catalog suggests, due to single digit precision, no precise measurement. Unfortunately, the glare of the primary did not allow the resolution of the "B" companion. The radius of the star disk of the primary was, in spite of exposures of less than 1 second, larger than the $A$ to $B$ separation. On the very positive side of this effort was the serendipitous discovery that the "D" component of JC1 was in actual fact made up of two very similarly bright (dim) stellar components.

Table 2: Photometry and measurement results based on iTelescope images used with AAVSO VPhot

1. Images for photometry taken with 1 s exposure time with telescope iT31 CDK $510 \mathrm{~mm} f / 6.8$ with 1.1 arcsec resolution per pixel and V-filter. Uploaded to AAVSO VPhot, plate solved and up to 5 images stacked. Separation and PA were calculated with the formula provided by R. Buchheim (2008) based on the UCAC4 values for RA and Dec.
2. No photometry done for M1 as WDS catalog value did not seem questionable.
3. Astrometry based on this image confirms, within the error range for a resolution of 1.1 "/pixel, the new UCAC4 coordinates for " $C$ " and therefore the new calculated Separation and PA. The WDS catalog data is quite different.

## Photometry and Measurement of Faint and Wide Doubles in Eridanus

Figure 1. JC1 (cutting from image with luminance filter)

JC1 D is listed in the WDS catalog with a +12.48 magnitude suggesting a measurement of the combined magnitude. UCAC4 lists for JC1 D the object 342003585 with corresponding +12.482 Vmag. Photometry with the identical setup as for Table 2 results in slightly fainter +12.605 mag for D. Separate photometry for $\mathrm{JC} 1 \mathrm{Da}, \mathrm{Db}$ based on another image (Figure 1) gives the values shown in Table 3.

The combined magnitude calculated with the formula according to Greaney 2012 results in +12.34 mag - this seems at odds with the above given values for the combined magnitude of JC1 D but photometry results for combined magnitude are obviously not this precise for objects with more than $\sim 1$ " separation so we assume the magnitude given for JC1 D respectively UCAC4-342-003585, is wrong for this very reason.

## Conclusions

First impressions were, with the exception regarding the A components of HJ 2187 and ARA 1976, completely confirmed by photometry. Photometry for JC 1 offered additional interesting results in terms of component D being itself a faint double. This example shows also that photometry for a combined magnitude of faint objects with approximately larger than 1" separation might result in questionable values.

Table 3: Measurements for JC1 Da,Db

| Name | WDS ID | RA | Dec | Sep | PA | M1 | M2 | Date | N |

#### Abstract

The Mt. Wilson Double Star Workshop was organized to provide a hands-on educational and research opportunity for students and amateur astronomers to learn and carry out astrometric eyepiece measurements of double stars. Due to the unique operating characteristics of the Mt Wilson 1.5 meter telescope and the limited time available for observations, a Bell \& Howell DNV16HDZ high definition video camera was adapted to a Celestron 12.5 mm astronomic eyepiece to record the position and separation of double star STF2448. This paper records the results of the team's observations and their techniques used to record and analyze the data.

## Introduction

Observations took place on the evening of July 9, 2013 using Mount Wilson Observatory's 1.5 meter telescope (located at approximately $38^{\circ} 13^{\prime} 24^{\prime \prime} \mathrm{N}$ and $118^{\circ} 03^{\prime} 29^{\prime \prime}$ W) (Figure 1). The Mt. Wilson Observatory staff measurements of sky quality indicated that seeing was on the order of 0.5 arc seconds for the viewing period. This was later verified by the CHARA array group. The seeing quality was independently verified by Dave Jurasevic, Mt. Wilson's Deputy Director, who was observing in the same location and reported 0.4 arc second seeing.

The Mt Wilson 1.5 meter telescope was operated in a bent Cassegrain configuration with a focal length of 2438 cm which gave a focal F-ratio of F/16. Combined with the Celestron 12.5 mm eyepiece and extraordinarily good seeing conditions, stars with separations less than 3 arc seconds were reviewed in the Washington Double Star Catalog (WDS) catalog for consideration.

Double star STF 2448 was selected as the target

Figure 1. The $1.5 m$ (60') telescope located on the Mount Wilson Observatory used in the astrometry measurements. This photograph was taken on the day of the observations.

## Astrometry of STF 2448 on the Mount Wilson 1.5 m Telescope with a Novel Video Eyepiece

double. The pair is well studied, with more than 70 prior observations, and had little change in separation and position angle over the period of these observations. This stability provided a good 'fixed' reference for validation of the measurement technique on the 1.5 meter telescope.

First recognized by Otto Wilhelm Struve in 1825, the double star STF2448 is located in the constellation Lyra. According to the Washington Double Star catalog, both stars are white in color (spectral type A3), their magnitudes are very similar at 8.75 and 8.8 , and they have small common proper motions ( $+000-010$ ). The last recorded separation was between two and three arc seconds (Mason et al., 2013).

Other identifiers listed by SIMBAD include WDS J19037+3545AB, ADS1222002AB, AG +35 1705, BD +35 3460, CCDM J19037+3545AB ,GC 26231, HD 177543, HIC 93596,IDS 19001+3536, 2MASS J19033966+3544349, PPM 82250, SAO 67752, TD1 23835. Its precise coordinates are Right ascension 19 03 39.66; and Declination +3544 34.4.

## Methodology

The telescope was fitted with a Celestron Micro Guide 12.5 mm astrometric eyepiece with no filter (Figure 2). The Bell \& Howell DNV16HDZ 46 mm $\mathrm{f} / 2.8-3.5$ high definition video camera was adapted to the Celestron astrometric eyepiece, with a 46 mm filter ring allowing recorded views of most of the eyepiece's back-lighted field. This configuration did not allow a full view of the compass ring in the astronomic eyepiece and was a limitation of the video method. The eyepiece was attached to the telescope, and then best focus was attempted by driving the secondary mirror to its closest possible position to the primary mirror. The secondary mirror reached focus at the limit stop so back

Figure 2. The bent Cassegrain eyepiece of the 1.5 meter telescope where the astrometric eyepiece was attached. Photograph was captured by the authors during observation period.
focus was not achievable to verify that the system was at optimum focus for the eyepiece.

## Calibration

Following verification of the double star brightness and separation, eyepiece telescope calibration was accomplished using a modified version of Frey's drift method (Frey, 2008). The bright single star Alshain in the constellation Aquila (RA 19'55' $188^{\prime \prime}$ Dec $+6^{\circ} 24^{\prime}$ $23^{\prime \prime}$ ) was selected as the reference star in accordance with the telescope altitude and azimuth limitations. The reference star was centered in the scope view and then positioned out of the field of view. The drive was disabled and the star was permitted to drift along the central ruler.

Data was collected using both the stopwatch and video capture method. The magnification and location of the star resulted in extremely fast drift times, making stopwatch measurements exceedingly difficult. Because of the difficulty using the stop watch, this method was abandoned and the video drift measurements were made and used for calibration. For the video data runs, the centering and stop drive process was repeated and recorded 10 times.

The drift time from the recorded video was calculated by running each of the videos frame by frame through the Adobe Premiere Pro CC video editing software. This allowed the star to be precisely positioned at the 20 tic mark and then run forward to the 50 tic mark, giving a one half scale drift (Figure 3). The centroid of the star was visually aligned with the start and stop tic marks.

The Premiere software displays the frame number at the start point and the end point for both tic mark alignments. The change between frame rates was obtained and then multiplied by the high definition camera recording sample rate of 59.96 frames per second. This number was doubled to obtain the full scale drift time. Each measured time was recorded in the double star Excel data sheet used for the night's observation runs. Several less capable software programs were tested, but the results were unreliable because the software dropped frames during the analysis. The Adobe Premiere software has a dropped-frame alarm that was activated during the analysis runs to ensure all the captured video frames were evaluated.

These average drift times were then used to calculate the scale constant Z , using the formula $\mathrm{Z}=$ [15.0411 $\cdot \mathrm{T}_{\text {average }} \cdot$ the cosine of the declination angle] divided by 60 (the number of reticule divisions, D) (Frey 2008). The formula can be expressed as:

$$
\mathrm{Z}=\left[15.0411 \mathrm{~T}_{\text {avg }} \cos (\delta)\right] / \mathrm{D}
$$

Astrometry of STF 2448 on the Mount Wilson 1.5 m Telescope with a Novel Video Eyepiece

Figure 3. A sample image taken from a video frame for the drift time calibration of the Alshain star. The image on the left represents the start point of the video time run while the image on the right is the image end point.

During the calibration measurements, the average drift time for ten runs was 3.34 seconds with a standard deviation of 0.05 , and a standard error of the mean of 0.02 was obtained (Table 1). A scale constant of 0.832 arc seconds per tic mark was also derived.

## Observations

Following calibration, the double star STF2448 was selected from Joseph Carro's modified WDS star catalogue and the position was verified using The Sky 6 software (Carro, 2013). The star pair was placed into the field of view and its identity was confirmed using its color and estimated separation. The close visual magnitude of the stars made it initially necessary to guess the primary and secondary orientation, with the prediction being supported by early data analysis pro-

Table 1. Calibration Data. The calibration drift time of the star Alshain was found to be $3.34 \pm 0.05 \mathrm{~s}$.

| Calibration Star | Drift Time <br> (sec) |
| :---: | :---: |
| Average Drift Time | 3.34 |
| Std. Dev. | 0.05 |
| Median | 3.30 |
| Standard Error of the Mean | 0.02 |
| Declination angle (rad) | 0.11 |
| Divisions | 60 |
| Scale Constant | 0.83 |

vided by the Excel worksheet used to capture data.
Separation estimates were determined using a combination of two methods. The pair of stars was placed along the linear scale and the number of scale divisions between the stars was estimated. In the first method, visual observation, the camera was detached and the team members looked directly through the eyepiece per Frey's procedure (Frey, 2008). Teammates were rotated through the visual stand on the telescope and ten data sets were recorded.

This was followed by re-installing the Bell \& Howell DNV16HDZ video camera onto the eyepiece. A single 30 -second HD video was captured (2000 frames) and still photographic capture runs were performed and recorded for later analysis.

During the following day's data analysis, another technique was developed by utilizing a rudimentary lucky imaging technique. Again, the video of the separation was evaluated frame-by-frame using Adobe Premiere Pro CC. The frames with the smallest, clearest star shapes and best scale alignments were selected for evaluation.

The next method used Adobe Photoshop Pro CC software to evaluate the video capture stills. The sample photos derived from the frame by frame analysis were displayed in the software and the digital ruler tool, available in the program, was utilized to measure separation using the following procedure.

The digital ruler displays a numeric value for the number of picture pixels between the two objects in the photograph. The ruler was used to measure the pixel separation of the stars from centroid to centroid. This number was then evaluated against the same delta ruler measurement of the pixel tic mark separation of the

Astrometry of STF 2448 on the Mount Wilson 1.5 m Telescope with a Novel Video Eyepiece

Figure 4: A screen shot of Adobe Pro CC software being used to analyze video still shorts. The image on the left is using a ruler tool to measure the eyepiece tic-to-pixel ratio while the image on the right is measuring star separation centroid to centroid. Note the extremely tight star spots; this is evidence of exceptional seeing conditions coupled with the superior optics of the 1.5 meter Mount Wilson Telescope.

Table 2. Using the video capture technique, the separation of STF 2448 was $2.1 \pm 0.16$ arcsec.

| Run | Divisions |
| :---: | :---: |
| Average | 3.07 |
| Std. Dev. | 0.16 |
| Median | 3.00 |
| Standard Error of the Mean <br> Average Div. x scale Con- <br> stant in Arc Seconds | 0.03 |
| Separation (Arc Seconds ) | 2.12 |

eyepiece scale using the same photograph (Figure 4). The stellar separation was then derived mathematically using a ratio of tic mark measurements versus star separation measurements.

The combination of the eyepiece and camera did not allow the inclusion of the eyepiece compass in the video field of view, resulting in the necessity of angle measurements being made visually, according to Frey's method (Frey, 2008). The most experienced team member, Chris Estrada, made all measurements because of observation time constraints. Following each measure-

Table 3. The calculated position angle of STF 2448 was $193 \pm 0.75^{\circ}$.

| Observation | Reading of <br> Eyepiece | Position Angle <br> Degree |
| :---: | :---: | :---: |
| Average | 103 | 193 |
| Std. Dev. | 0.75 | 0.75 |
| Standard Error of the <br> Mean | 0.17 | 0.17 |

ment, the tracking feature was enabled and the process was repeated 10 times. All of the data was captured on an Excel spreadsheet that was automated to perform the necessary mathematical calculations.

## Observational Results

The separation of STF 2448 was calculated to be 2.1 arc seconds within a standard deviation of 0.16 arc seconds. The position angle was measured at $193^{\circ}$ with a standard deviation of $0.75^{\circ}$ (Tables 2 and 3). Table 4 gives our observational results. Table 5 depicts previous recorded measurements of the STF 2448 double star as well as the values calculated using our data.

## Conclusions

Overall, the use of the Celestron 12.5 mm astronomic eyepiece on the telescope and the video capture method were successful. The setup afforded a focal length of 24.3 m and magnified the field of view to $1,950 \mathrm{X}$ power. This, along with the 1.5 meter aperture,

allowed for adequate visual split against the eyepiece scale of this close double as well as significant star brightness of the near magnitude 9 star pair. With this eyepiece and focal length combination, it was possible to measure stars down to 2.5 arc second separation, nearly an order of magnitude closer than those measured by Frey's astrometric visual observations (Frey, 2008). During later analysis of video data, several frames were noted for having excellent seeing and focus that produced pinpoint star images with adequate stable separation. The night's work was validated by the position angle and separation measurements agreeing with previously established observation methods within the sky seeing limits.

Results indicate that video capture of separation information and drift time offers an effective way of collecting astrometric data. The compact size, portability, and easy setup of the camera and eyepiece combination offer a viable research tool that could be adapted to many telescopes, from the very large observatory grade scopes to the small amateur-owned systems. The ability to capture the high fidelity raw data during the run on the telescope and store it for later analysis was evaluated and found to be very useful. Despite the technique's advantages, further development is needed in the eyepiece-adapter connection in order to include the compass scale in the camera's field of view. Additionally, it was shown that evaluation of video data should be accomplished on robust video editing software, because errors in playback and frame drop were evident when using products like Microsoft Movie Maker and ArcSoft Total Video Extreme.

Future work necessary to extend this investigation is two-fold. First, the position angle and separation of STF2448 should continue to be measured in order to make calculating an accurate orbit possible. Second, more measurements need to be made of other stars with other telescopes in order to verify the effectiveness of the video capture method. In this experiment, it was not possible to back-focus the telescope because of mirror motion limitations, so sightings recorded with a telescope that has been verified to be properly focused would be beneficial. Finally, a study in the properties of various video playback and editing software is necessary in order to develop a more standard procedure of the video analysis portion of the measurements.

## Acknowledgments

We thank Cheryl Genet and Inga Kenney for their help in organizing the event, and the management and staff of the Carnegie Foundation and the Mt. Wilson Observatory for allowing us to use the magnificent 1.5 meter telescope. We also thank the US Naval Observatory for extensive use of the Washington Double Star Catalog. A special thanks goes to Joseph Carro for organizing the WDS catalog into a usable computer database format. Finally, we thank the reviewers of this paper for their helpful suggestions.

# Double Star Measurements Using a Webcam and DSLR, Annual Report of 2014 

Joerg S. Schlimmer<br>Seeheim-Jugenheim, Germany<br>Email: js@epsilon-lyrae.de

#### Abstract

I report on 138 double star measurements from 2014; minimum separation is 1.4 as (STF 401 AB ), maximum separation is 400.6 as (SMR 13AE). The mean value of all measurements is 82.6 as.

## Report

This is a report of 138 double star measurements from 2014 made with a standard webcam ( 81 measurements) and a DSLR camera ( 44 measurements). In 11 further cases measurements was done in both ways. Minimum separation is 1.4 as, maximum separation is 400.6 as. The mean value of all measurements is 82.6 as.

Measurements were done with a 12 -inch Newtonian telescope. A detailed description of the optical setup is given in annual report of 2012 (Schlimmer, 2013). Reproduction scale is about 0.77 as for webcam measurements and 0.70 as for DSLR images. In case of DSLR imaging an additional coma corrector was used. In both cases data analyses were done with REDUC software.

Focus of observation in 2014 was stars of Max Wolf's "Catalog About 1053 High Proper Motion Fix Stars" (Wolf, 1919) which are already listed in Simbad Database as well in WDS catalog. There are only 94 matches, because most of Wolf's stars aren't double stars (Schlimmer, 2014). This review is not yet finished and will be continued in 2015. In the notes column of table 1 eighteen of these stars are remarked with Wolf's number as listed in Simbad Database.

During observations of 30/31 Cygni in late summer of 2014 some further companions could be found. Also a further double star in the neighborhood could be found. These discoveries are described below.

## WDS20136+4644, 31 Cygni

Next to components H and F further companions

Figure 1. 30/31 Cygni with companions of $H$ and $F$, exposure time $4 \times 180 s$
could be found (see Figure 1). The distances are 9 as for H1 and 3.6 as for F2. The position angles are 263 degree and 214 degree. The estimated brightness of these companions is about 0.5 magnitudes lower than the associated primaries.

## Double Star Measurements Using a Webcam and DSLR, Annual Report of 2014

## USNO-B1.0 1366-0359784

This object is next to 31 Cygni is listed as single star in the catalogs. I found 2 components in a distance of about 7 as and a position angle of 59 degree (see figure 1). Coordinates are $20139+4641$. The brightness is 12.14 magnitudes ( B 1 mag ) for both components. There is a small proper motion of $10 \mathrm{mas} / \mathrm{yr}$ in R.A. and $4 \mathrm{mas} / \mathrm{yr}$ in declination. Therefore USNO-B1.0 13660359784 is a possible common proper motion pair.

Table 1 shows the measurements of 136 double stars from 2014.

# Measurements of BU109 in Cetus 

Wilfried R.A. Knapp<br>Vienna, Austria<br>wilfried.knapp@gmail.com<br>John Nanson<br>Star Splitters Double Star Blog<br>Manzanita, Oregon<br>jnanson@nehalemtel.net<br>Chris Thuemen<br>Double Star Imaging Project<br>Pembroke, Ontario, Canada<br>thuemen_cm@yahoo.ca

#### Abstract

Images of BU109 in Cetus raised questions about magnitudes and positions of components as listed in the WDS catalog, the most valuable resource for double star observers. Further research suggested changes for magnitudes and positions and questioned whether the most recent listed precise measurements are always the most precise measurements.

## Introduction

An image of BU 109 taken by Chris Thuemen in August 2012 and only recently presented on the Double Star Imaging Project Yahoo Group Site suggested magnitudes and positions of components B and C to be very different from the then current WDS data.

For illustration purposes, we show the relevant part of this image in negative grey scale and enhanced contrast demonstrating the components being very closely aligned in a straight line (Figure 1). A summary of WDS 2014.96 data is given in Table 1.

For comparison, the data of the corresponding UCAC4 objects:

BU109 B: UCAC4-368-000777 + 11.092mag model fit and 11.068 aperture photometry, no Vmag. These values indicate that the WDS data might need a correction for the magnitude of component B

BU109 C: UCAC4-368-000778 +11.246mag model fit, +11.223 mag aperture photometry and 10.696 Vmag . While the latter value seems somewhat questionable,

Figure 1. BU 109 (grey scale negative with gamma correction)

## Measurements of BU109 in Cetus

Table 1: WDS 2014.96 values for BU109

| Name |  | WDS ID | RA | Dec | Sep | PA | M1 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| BU 109AB | $00405-1631$ | $00: 40: 28.560$ | $-16: 30: 59.800$ | 97.5 | 356 | 6.6 | 9.1 |
| BU 109AC | $00405-1631$ | $00: 40: 28.560$ | $-16: 30: 59.800$ | 94.9 | 355 | 6.6 | 9.4 |
| BU 109BC | $00405-1631$ | $00: 40: 27.740$ | $-16: 29: 14.503$ | 11.7 | 160 | 9.1 | 9.4 |

these values indicate that the WDS data might need a correction for the magnitude of component C .

The image taken by Chris Thuemen, as well as the DSS and 2MASS images, show clearly that the components $\mathrm{A}, \mathrm{B}$, and C are more or less in a straight line. If the separation of $11.7^{"}$ for BC is correct, then at least one of the separations AB or AC is in error.

Regarding separation AB or AC : as the WDS cata$\log$ includes position for A (in object AB ) as well as for $B$ (in object BC) it is easy to calculate separation and PA based on the formula provided by R. Buchheim (2008). Separation AB, based on this formula, is therefore 106.46 " and PA is $351.53^{\circ}$ - so the evidence for the separation error AB was contained in the WDS data.

## 2. Further Research

### 2.1 Additional images

To investigate further our initial findings, we concluded that the best approach would be to obtain a new image suitable for photometry and astrometry.

A single frame image of a 10 s exposure was taken with an online $320 \mathrm{~mm} \mathrm{f} / 9.3 \mathrm{RC}$ telescope having a resolution of 0.8 seconds per pixel and equipped with a V filter, located in Siding Spring, Australia. Photometry was based on several UCAC4 Vmag (APASS) listed stars within the field of the double star system for the purpose of comparing and checking the new magnitude values against those listed in the UCAC4 catalog. The resulting values are included in Table 2.

In Table 3 we list the UCAC4 RA/Dec coordinates for
the BU109 components.
Using the formula provided by R. Buchheim (2008), new separation and position angles were calculated (Table 4) based on the UCAC4 values which are assumed to be the currently most precise available coordinates.

The UCAC4 based results in Table 4 are within a reasonable margin of error and in line with the estimated astrometry results based on the iTelescope image in Table 2, while the WDS catalog data, and in particular that for AB , is quite different and obviously in error.

In the next step we presented these findings to the USNO and suggested magnitude changes for BU109 B and C as well as a correction of separation AB .

This resulted in the following WDS updates in changes of estimated magnitudes for B to +10.4 mag and C to +10.7 mag and of separation AB to $105.6^{"}$.

### 2.2 Research in the history of BU109

First, with regard to the apparent error regarding the separation of either AB or AC as shown in Table 1, let's look at the AB separations listed in the WDS text file for BU 109. The 2003.809 separation of $97.48^{\prime \prime}$ for AB (shown in Table 1) stands out as being significantly closer than any of the prior measurements. When we discard the three most anomalous measures in the text file (the 1980.000 separation of 120 ", the 1990.761 separation of 125.50 ", and the 2003.809 separation of $97.48^{\prime \prime}$ ), we get an average separation for AB of 104.05 " from the other nine measurements.

Table 2: Results based on iTelescope image used with AAVSO VPhot

| Name | RA | Dec | M2 | M2 Err | Sep | PA | Date | N | Notes |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| BU 109AB | $00: 40: 28.664$ | $-16: 30: 59.529$ | 11.130 | 0.041 | 106.17 | 353.22 | 2015.008 | 1 | $1)$ |
| BU 109AC | $00: 40: 28.664$ | $-16: 30: 59.529$ | 11.276 | 0.041 | 95.21 | 354.81 | 2015.008 | 1 | $1)$ |
| BU 109BC | $00: 40: 27.806$ | $-16: 29: 13.838$ | 11.276 | 0.041 | 11.31 | 159.78 | 2015.008 | 1 | $1)$ |

Notes:

1. Image for photometry taken with a single10s exposure with telescope iT9 RC $320 \mathrm{~mm} / 9.3$ having a 0.8 arcsec resolution per pixel c/w V-filter. Uploaded to AAVSO VPhot and plate solved. RA/Dec coordinates, Separation and PA are estimates calculated with the tools provided by AAVSO VPhot. No photometry done for M1 as the WDS catalog value for BU109A did not appear questionable.

## Measurements of BU109 in Cetus

Table 3: RA/Dec positions based on UCAC4 coordinates

| Name |  | UCAC4 ID | RA |
| :---: | :---: | :---: | :---: |
| BU 109A | $368-000780$ | $00: 40: 28.582$ | $-16: 31: 00.047$ |
| BU 109B | $368-000777$ | $00: 40: 27.739$ | $-16: 29: 14.462$ |
| BU 109C | $368-000778$ | $00: 40: 28.009$ | $-16: 29: 25.153$ |

Next, because all three stars are very close to being in alignment with one another, it should be possible to determine the separation of $A C$ by subtracting the BC separation from the AB separation. When that operation is performed on the data in Table 1, it results in a separation for AC of 85.8 ", which is in notable disagreement with the 94.9 " separation for AC shown in Table 1 , as well as with the history of AC.

We can perform the same operation using the WDS data that immediately precedes the Table 1 data which was current at the time Chris Thuemen's image was taken. From the WDS text file, that would be the 1999.637 data for AB and AC , and the 1999.641 data for BC , all of which come from the same source (AJ 146, 76, 2013).

The 1999.637 separation for AB is 105.634 " and the 1999.641 measure for BC is 11.393 ". Subtracting $B C$ from $A B$, we get a separation of 94.241 " for $A C$.. Looking at the actual 1999.637 measure for AC, we find a separation of 94.91 ".

In other words, the assumption that the separation of AC can be determined by subtracting BC from AB because all three components are more or less in line, works with the 1999 measures because they're all consistent with each other. It also works with Burnham's 1898.79 measures: 103.05 " (AB) minus $11.24 "$ (BC) equals 91.81 ", which matches well with Burnham's 1898.69 AC separation of $91.90^{\prime \prime}$.

The reason that method fails to work with the 2003.809 separation for $A B$ is because the 2003 measure of $A B$ is in error.

Looking further into the history of the AC and BC measures in the WDS text file, we find the measures of both are rather consistent, apart from the first estimates by S.W. Burham in 1873, which he later improved on with precise readings in 1900.

The first magnitude we have for B is Burnham's estimate of 10 in 1873. It stays in that range until a 1916.84 reading of 12.2 and then drops to a 10.7 reading very quickly as of 1916.85 . The magnitude of B then increases to 10.3 in 1917, increases again to 9.4 in 1980, then in 1998 is assigned values of $10.055,9.770$, and 9.726 , all coming from 2MASS data. As of

Table 4: Separation and position angle based on UCAC4 coordinates

| Name |  | Sep | PA |
| :---: | :---: | :---: | :---: |
| BU 109AB | 106.28 | 353.45 |  |
| BU 109AC | 95.25 | 355.04 |  |
| $B U \quad 109 B C$ | 11.37 | 160.04 |  |

1999.641, B was reduced to a magnitude of 11.09 , which is the UCAC fit model value (from this source, previously cited: AJ 146, 76, 2013). The 11.09 value is the last magnitude listed in the WDS text file.

However, and this is where confusion enters the picture, the magnitude value we found listed for B in the WDS as of 2014.96 (Table 1) was 9.1. That value is also listed in an earlier version of the WDS downloaded into an Excel spreadsheet on 2014.44. At any rate, as a result of correspondence with the WDS on our initial findings, the magnitude of B was changed to its present value of 10.4.

For C, the pattern is very similar, again starting with an estimate of 10 in 1873 by Burnham, a low point of 12.0 coming on 1916.84, a gradual increase to 9.6 in 1980, followed by 2MASS values in 1998 of 10.155 , 9.857 , and 9.837 . The final reading in the text file is the 1999 UCAC4 value of 11.25 , which again is the UCAC fit model value. But, as we found with B, the magnitude value listed for C in the 2014.96 (Table 1) and 2014.44 versions of the WDS was a different number, specifically 9.4. Following our correspondence with the WDS, that value has now been changed to 10.7.

## 3. Conclusions

First impressions were completely confirmed by photometry and astrometry done on a recently taken image. It should be pointed out that the most recent measures listed in the WDS may be in disagreement with prior WDS measures, which is another way of saying the most recent measure may not be the best available measure. Therefore, if questions regarding the precision of current WDS parameters arise, it seems necessary to check first the historical record contained in the WDS text file of such a double in order to determine if there is a quality problem with the last recorded measurement.

## 4. Further Plans

Given that the current WDS data for BU 109 appears to have room for improvement, especially for magnitudes B and C as well as to some degree in RA/ Dec coordinates respective Theta and Rho, we intend to

## Measurements of BU109 in Cetus

do further imaging on BU 109 as soon as there is again, sufficient altitude for imaging so that new photometry and astrometry data can be collected to obtain as precise measurements as possible to further improve the WDS data on this object.

#### Abstract

To initiate a long term binary star research program, undergraduate students compared the accuracy and ease of measuring the separations and position angles of three long period binary pairs using three different measurement techniques. It was found that digital image capture using BackyardEOS software and subsequent analysis in Adobe Photoshop was the most accurate and easiest to use of our three methods. The systems WDS J17419+7209 (STF 2241AB), WDS 19418+5032 (STFA 46AB), and WDS $16362+5255$ (STF 2087AB) were found to have separations and position angles of: $30^{\prime \prime}, 16^{\circ} ; 39.7^{\prime \prime}, 133^{\circ}$; and $3.1^{\prime \prime}, 104^{\circ}$, respectively. This method produced separation values within $1.3^{\prime \prime}$ and position angle values within $1.3^{\circ}$ of the most recently observed values found in the Washington Double Star Catalog.

## Introduction

During September and October of 2014 seven undergraduates and two faculty members from Keene State College (KSC, Figure 1) compared three different methods to measure separations and position angles (PA) of binary stars: direct measurement through a micrometer reticule eyepiece, analysis using the software package BackyardEOS, and through captured images evaluated in Adobe Photoshop.

KSC has made it a priority to provide students of any discipline the opportunity to conduct meaningful undergraduate research. KSC physics faculty members attended the 2014 Stellafane Workshop on Binary \& Multiple Star Astronomy to evaluate the potential of initiating an undergraduate binary star research program. After the daylong experience they felt confident that this work could be implemented at KSC and make significant contributions to binary star research. Our logical first step was to evaluate and develop the best methods available to collect and analyze binary star data. Here we present our results from data collected during the fall semester 2014, our first steps in implementing a long term research program. The majority of the measurements were taken at Otter Brook Dam in Roxbury, NH (chosen due to the dark skies and proximity to the college) and the

Figure 1: Researchers from left to right: Adjunct Professor Keith Goodale, Students: Ian Ross, Andrew Penfield, Cory Boulé, Trisha Braught, Katelyn Andrews, Ryan Walsh, and Professor Steven Harfenist.
remaining measurements were made along Apian Way on the KSC campus (introducing some difficulties in acquiring data due to the ambient light pollution).

The stars WDS J17419+7209 (STF2241AB-Psi Draconis), WDS 19418+5032 (STFA 46AB - 16 Cygni), and WDS 16362+5255 (STF2078AB - 17 Draconis) were chosen for our methods comparison due

Figure 2: (a) The illuminated Celestron MicroGuide Eyepiece and (b) image of the micrometer reticule scales used to make separation and position angle measurements.
to their relatively long orbital periods ( $\sim 104$ year, division) were calculated using the equation: Kisselev 2009, Hauser \& Marcy 1999, Tolbert 1964), which ensures there will be no noticeable change in separation or PA enabling comparison with recent measurements found in the Washington Double Star catalog (WDS) (Mason \& Hartkopf 2013). Their seasonal visibility and the fact that they are bright and relatively easy to locate made them logical choices for us. A detailed discussion of the three methods is given below.

## Equipment and Methods

A 9.25 inch $(\mathrm{f}=2350 \mathrm{~mm})$ Celestron SchmidtCassegrain telescope (SCT) on a computerized Orion Atlas equatorial mount, a Celestron MicroGuide Eyepiece (Figure 2a), a 2 X Barlow lens, a Canon digital single lens reflex (DSLR) camera mounted to the back of the telescope (at prime focus), and a laptop computer were utilized for the observations. For all digitally captured images, BackyardEOS was used (Nikon DSLR users would use BackyardNik, see http:// www.otelescope.com). Digital analysis was performed using both BackyardEOS and Adobe Photoshop. For the micrometer reticule and Backyard EOS analysis methods, each student made measurements of separation and PA. A group average was calculated which was then compared to the WDS values.

The reticules provided a linear scale and a $360^{\circ}$ protractor (Figure 2b, Figure 3). The linear scales were calibrated using the drift method (Teague 2012). After the clock drive was turned off, the time for the star Altair to drift across the linear scale was measured. Each researcher made measurements of the time it took for Altair to drift across the linear scales for both BackyardEOS and the reticule eyepiece. These times were averaged and the scale constant ( $Z$, number of arc seconds per

$$
Z=\frac{15.0411 \cos (\delta) t}{N}
$$

Here, $t$ is our average drift time in seconds, $\delta=$ $8.8683^{\circ}$ is the known declination (epoch j 2000.0 ) in arc seconds of Altair, $N$ is the number of divisions swept in time $t$, and the coefficient 15.0411 is the Earth's angular rate of rotation in arc seconds per second. The value of $Z$ for the micrometer reticule eyepiece was determined to be 4.0" per division and 7.8" per division for BackyardEOS.

## Measurement with MicroGuide Reticule Eyepiece

Separation measurements were performed by first centering the primary in the crosshair, aligning the two components on the linear scale through rotation of the eyepiece, and then the number of divisions between each star image's centroid was recorded (Figure 2b). The eyepiece was then rotated $180^{\circ}$ and the same measurement made to reduce systematic error. All division measurements were converted to arc seconds using the value of $Z=4.0^{\prime \prime}$ per division. Separation standard deviations were found following the procedure outlined in Weise, et. al., 2014.

To determine the PA for each pair, the primary was centered in the reticule and oriented such that the $0-180^{\circ}$ line of the protractor was aligned along the line segment joining the pair of stars. With the clock drive turned off the stars drifted across the outer protractor scale from east to west, enabling the direction of west to be determined. In a SCT used with a star diagonal, north will be $90^{\circ}$ clockwise from west. North is $0^{\circ}$ and the PA is

## Determining the Separation and Position Angles of Orbiting Binary Stars: Comparison of Three Methods

Figure 3: Screen capture image showing the protractor and linear reticule scales for performing drift alignment in BackyardEOS, here used to make separation and PA measurements. Note that only one half of the linear scale was used since the width of the center division is variable.
measured eastward from north.

## Measurement with BackyardEOS

BackyardEOS is a versatile astrophotography software package that provides complete control for capturing digital images with Canon DSLR cameras. We used the premium version of BackyardEOS 3.0.3 that provides a reticule and protractor as shown in Figure 3. The reticule is ordinarily used for drift alignment when polar aligning the mount, but here we explored its use in making position angle and separation measurements of binary pairs. Separations were measured in the field using the reticule in Live View mode, while PA measurements were performed using the protractor in Drift Align mode, which stacks Live View frames into one image file as the pair drifts with the clock drive turned off (see Figure 4). The image file for the PA measurement was saved and analyzed at a later time.

The same measurement procedures were followed as performed with the reticule eyepiece, with two exceptions: the linear reticule scale in BackyardEOS was calibrated using only half the scale to avoid complications with the variable width drift alignment crosshairs in the center and north will be $90^{\circ}$ counterclockwise from west. One advantage of this software is that it allows the user to enlarge the screen image (at the same resolution), better facilitating the separation measurement of the two stars (see upper right hand corner of screen capture in Figure 3). Since the resolution is limited by the software in Live View mode, a disadvantage is that close pairs can be difficult to split on the computer screen.

## Measurement with Adobe Photoshop

Digital images of binary pairs captured in BackyardEOS were made at ISO 800 using short exposures from 1-10 seconds depending on the brightness of the pair. A separate 15 -second exposure was made with the pair initially centered in the field and the clock drive disengaged. This produced a star trail that indicated west as the pair drifted across the field during the exposure.

The images were later opened in Adobe Photoshop for analysis. Photoshop's Measure tool was utilized for measuring the separation between the centroid of each component of the pair in pixels (Figure 5). The PA was determined using the Measure tool in angle mode of an overlay of both the short exposure and the 15 second trailed exposure (Figure 6). The pixels to arc second conversion is defined by the focal length of the telescope and the sensor size of the camera. The following formula (Wilmslow Astro website, http:// www.wilmslowastro.com/software/formulae.htm) may be used to calculate arc seconds per division when using small angles:

$$
\text { arc seconds } / \text { pixel }=\frac{\text { pixel }[\mathrm{mm}]}{f[\mathrm{~mm}]} \times 206,265^{\prime \prime}
$$

The Canon manufacturer's specifications for the 60Da camera model specify a pixel size (pixel) of 4.3 $\mu \mathrm{m}$ and Celestron lists the focal length $(f)$ of the telescope as 2350 mm . The value of $206,265^{\prime \prime}$ converts the angular field of view of one pixel in radians to arc sec-

## Determining the Separation and Position Angles of Orbiting Binary Stars: Comparison of Three Methods

Figure 4. Position Angle determination in BackyardEOS. A 45 second drift image of 16 Cygni (STFA 46AB) is used to determine west. The primary is centered on the protractor scale which is rotated to align the pair along the $0-180^{\circ}$ line. The $P A$ is then measured from north counter clockwise to the $0-180^{\circ}$ line, here measured to be $133^{\circ}$.
onds. Using the formula above, the number of arc seconds per pixel for our telescope and camera combination is .377 .

Separation measurements using Photoshop began with zooming on the pair in the short exposure image. We placed the Measure tool cursor (in Ruler mode) on the primary star and clicked and dragged the tool out to the secondary component, producing a line between the two stars (Figure 5). Further enlargement of the image and minor corrections in the cursors' locations allowed more accurate centering of the Measure tool endpoints on each star's centroid. We then recorded the number of pixels between the pair, which were later converted to arc seconds. For our purposes here, a reasonable estimate of the separation measurements' largest uncertainties is the half width at half maximum of the widest intensity profile from each star pair. We estimate these values to be $3.4^{\prime \prime}$ for 16 Cygni, 3.8 " for $\psi$ Draconis, and 1.4" for 17 Draconis.

Position angle measurements were determined by using both the short exposure and the 15 -second drift exposure images simultaneously (Figure 7). The drift image was copied and pasted as a second layer into the short exposure image. The transparency for the top layer was changed to approximately $30 \%-40 \%$ to line up the two stars in the short exposure with the initial location of the stars in the trailed image.

The Measure tool (Angle mode) was placed at the primary star's initial position and traced along the star trail to indicate west. As with separations, further zoom-

Figure 5. Separation determination using Photoshop's Measure tool. In ruler mode the separation of Psi Draconis is found to be 77.88 pixels $=29.4^{\prime \prime}$.

Figure 6: Photoshop's Measure tool in Angle mode used to measure the PA of 16 Cygni as $133.3^{\circ}$. North is directed almost straight up in the image.
ing of the trailed image enabled more accurate correspondence between the drift direction and Measure tool orientation. Double clicking on the initial crosshair of the Measure tool initialized the Angle measurement mode that provided a second line/leg to measure angles. This new leg was rotated 90 degrees counterclockwise from west to determine north. Once north was found, the Measure tool was dragged, as a whole, such that the vertex was centered on the primary star in the un-trailed image without changing the orientation of the north pointing leg. Setting the transparency back to $0 \%$, the remaining leg of the measurement tool was then swept so as to pass directly from the center of the primary through the center of the secondary. The position angle was then measured from north $\left(0^{\circ}\right)$ counterclockwise to the line made from the primary to the secondary.

## Discussion

In recent years the micrometer reticule eyepiece has all but replaced the traditional filar micrometer, making

## Determining the Separation and Position Angles of Orbiting Binary Stars: Comparison of Three Methods

Figure 7: Position angle determination in Photoshop. A five second exposure is overlaid with a trailed 15 second exposure (transparency $\sim 40 \%$ ). West is determined from the direction of the drift and north is known to be $90^{\circ}$ counterclockwise from west using this method.
for dramatic improvements in ease of measurement at lower cost. More recently, digital capture and analysis of astronomical images has begun to replace those made at the eyepiece. Our results show that digital measurements are not only more precise and accurate, but much easier to implement. However, we do find that a micrometer reticule eyepiece is still a valid method of measurement, whose accuracy can approach digital methods if care is taken during measurement.

Table 1 compares the three measurement techniques' values found for each of the three binary pairs. Compared to the WDS, it was found that Photoshop gave the most accurate results, followed closely by BackyardEOS and then the micrometer eyepiece. Even though BackyardEOS is not intended for this type of measurement, data analysis using its protractor and linear scale produced results comparable to those found with analysis in Photoshop for wider separated pairs.

Photoshop analysis provided separation values within $1.3^{\prime \prime}$ and PA values within $1.3^{\circ}$ from the WDS values. BackyardEOS analysis provided separations within $1.3^{\prime \prime}$ and PA data values within $2^{\circ}$ from WDS values. This data does not include 17 Draconis, which could not be split by BackyardEOS in Live View mode. The micrometer eyepiece measurements had separation deviations between $0.8^{\prime \prime}$ and $1.9^{\prime \prime}$ and PA deviations between $1^{\circ}$ and $3^{\circ}$ from WDS values.

All of our methods suffer from the systematic uncertainties caused by the flaring of scattered light due to atmospheric seeing combined with optical aberrations. The micrometer reticule has additional measurement error associated with the parallax experienced while looking through the eyepiece, especially for novice as-
tronomers. At times atmospheric turbulence made the closely separated pairs quite difficult to measure with respect to centering the primary on the protractor and aligning the pair along the $0^{\circ}$ to $180^{\circ}$ line. Even so, with meticulous attention made using the micrometer reticule, the accuracy of this method could certainly approach that of Photoshop analysis.

The advantages of analysis in Photoshop are numerous. It provides the best separation measurement resolution ( $\pm 1$ pixel $/ \pm 0.377$ "). The precision of the Measure tool in Angle mode $\left(\sim 0.01^{\circ}\right)$ is much better than those made in the field by eye on a protractor reticule (smallest division of $5^{\circ}$ ). Last, data analysis can be performed indoors at a later time, minimizing time spent in the field. The main disadvantage is the cost of the software ( $\sim 600 /$ year for a new user) and the need of a computer for analysis (if using a computer in the field, additional image capture software will be required, such as BackyardEOS, MaxIm DL, IRIS, or Nebulosity)

The use of BackyardEOS for these measurements employs nearly identical methodologies as the micrometer reticule eyepiece, but with a few advantages. Measurements can be made on a computer screen that can zoom in on the image. It also enables easier centering of the stars, having the capability to move and rotate the scales to the objects of interest. BackyardEOS does have some disadvantages when used in this way. As with the micrometer reticule eyepiece, it uses a linear and protractor scale to make measurements and is subject to human measurement error. Its Live View resolution is dependent upon good seeing to split close binaries, often requiring many various duration exposures and ISO settings. Even so, some binaries were not resolvable (STF2078AB -17 Draconis).

The micrometer eyepiece has the advantage of utilizing the human eye's ability to capture short moments of good seeing, it can be used with a Barlow lens, and has higher magnification than BackyardEOS implemented in this way with a Canon DSLR camera (this version of BackyardEOS only works with Canon EOS DSLR cameras). A further disadvantage of the micrometer eyepiece is that they are becoming harder to find since they are being produced more infrequently as digital capture and analysis methods become more common, affordable, and versatile.

## Conclusion

We found that all three measurement methods are valid, but will continue to focus on using BackyardEOS for image capture and Photoshop for analysis in the immediate future, as we found this combination to work best for us. Going forward, our undergraduate research group will continue to catalog binary stars with the aim to image and analyze close binary pairs, those with larg-

# An Online Tool that Searches the WDS 

T. V. Bryant III<br>Little Tycho Observatory<br>703 McNeill Road, Silver Spring, Md 20910<br>rkk_529@hotmail.com

#### Abstract

An online tool that extracts entries based on user input from the Washington Double Star Catalog (WDS) ${ }^{1}$ has been created. It can be found at: http://mainsequence.org/html/wds/getListOfDoubles/mkWDS_List.html

The data in the Washington Double Star Catalog are currently scattered over several files. Researching it requires perusing these files to find all of the data related to a given star, a time-consuming activity. To ameliorate this, the author has built a series of computer programs that assemble most of these data for a given group of binaries into a single, online, color-coded list.

When the web site at http://mainsequence.org/html/ wds/getListOfDoubles/mkWDS_List.html is accessed, an initial menu is displayed as shown in Figure 1.

The top four fields are for the right ascension and declination boundaries of the region you wish to search. These must be filled out, or the program will not run and it will return an error message to you.

The next four fields, labeled"Other parameters", specify the criteria for the search you're about to make. They are filled out with default parameters that you will probably want to change.

- Faintest primary star to list: The magnitude of the faintest primary star to be included in the list.
- Maximum magnitude difference between primary and secondary: Binaries with a greater brightness difference will not be in the list.
- Maximum separation between primary and secondary: Binaries with a greater separation will not be in the list.
- Minimum separation between primary and secondary: Binaries with less separation will not be in the
list.
Clicking the Submit button will create the list.
The columns in the list are described in the explanation section, which can be accessed by clicking the "Explanation" tab in the third line of the list's header. It is reproduced in the following paragraphs:

The data in this list is a compendium of the United States Naval Observatory's main catalog, neglected stars, notes, and alternate star name list. The data in your list are taken from these documents and filtered according to your submitted specifications.

Row color explanation:

- A pair shown in green means that the data for the pair are probably accurate.
- A pair shown in yellow means that the WDS has listed the pair as neglected.
- A pair shown in red means that the pair has not been observed since 1970 or its last observation date is unknown.

Note: The data listed for all pairs are accurate, irrespective of the highlight color. The USNO gives a detailed explanation of neglected stars. Click here to go there.

The J2000 coordinates are formatted such that they can be copied into tools such as

An Online Tool that Searches the WDS

## Get the WDS stars in a given region.

Please use this format for right ascension: hh:mm:ss.ss
Example: 05:37:12.31
For integer hours, only the number is required, e.g. 5 hours can be entered as " 5 "
Western right ascension boundary:
Eastern right ascension boundary:
Please use this format for declination: +/-dd:mm:ss.ss
Example: -36:43:34.57
For integer degrees, only the number is required, e.g. $30^{\circ}$ can be entered as " $30^{\prime \prime}$
Northern Declination boundary:
Southern Declination boundary:
Other parameters:
Faintest primary star to list: 9.0 mv
Maximum magnitude difference between primary and secondary: 4.0
Maximum separation between primary and secondary: 60 arc seconds
Minimum separation between primary and secondary: $\begin{aligned} & 0.5 \\ & \text { arc seconds }\end{aligned}$
Submit
Figure1. Initial menu displayed at http://mainsequence.org/html/wds/getListOfDoubles/mkWDS_List.html, to be filled out by user to search the WDS.

## An Online Tool that Searches the WDS

(Continued from page 164)
Aladin or WikiSky to display the DSS image at that location. The wDS Id is a 10 digit string that lists a low precision coordinate of the pair. The Dsc Id gives the discoverer's initials or designator, and the number of the pair in their published list. A mv is the visual magnitude of the primary. Other bandpasses for a pair are described in the notes column. $\mathrm{B} \mathbf{m v}$ is the visual magnitude of the secondary. Spectra is the spectral type of the primary. At times the secondary's spectrum is listed as well. First and last $\theta$ are the earliest and most recent position angles of the pair, in degrees. First and last $\rho$ are the earliest and most recent separations, in arc seconds, of the pair. First and last Obs are the first year the pair was observed and the year of the most recent observation. AKA (Also Known As) lists other common names for the pair. Comments:

- Blue mags indicates that the pair's magnitude is photographic, Johnson, or other Blue band.
- Red mags indicates that the pair's magnitude is from the Johnson or other Red band.
- Dubious indicates that the pair is listed is probably an error in the original discoverer's listing.
- IR mags indicates that the pair's magnitude is its infrared magnitude. Usually 4-6 mags brighter than the visual magnitude.
- Linear indicates that linear elements for this pair have been determined.
- Low precision coordinates indicate that the precise position of the pair is not known.
- Neglected indicates that the pair is listed as neglected by the WDS.
- Orbit indicates that the pair is in the USNO's orbit catalog.
- Optical indicates that the pair is probably not physical.
- Uncertain indicates that the identification of the pair is uncertain.
- Uncertain Position indicates that the pair's position is uncertain.
Notes: If a star has an entry in the WDS notes document, the word "Note\#\#" where \#\# is the number of the note appears in this column. Clicking on it will take you to the text of that note.

## Notes

The search results are limited to a maximum of 500 binaries. After 500 binaries have been found, the search stops and the results are displayed.

The WDS is updated on a regular basis. The author attempts to update the database that contains the data shown by this list on a weekly basis as well.

# New Common Proper-Motion Pairs with R.A. Between 00h and 01h 

Rafael Caballero<br>Agrupación Astronómica Hubble, Martos, Jaén, Spain<br>Email: rafacr@ucm.es

#### Abstract

This paper presents 37 new common proper-motion pairs. The new pairs have been obtained employing a semi-automatic procedure based on the inspection of images using the tool Aladin, completed with information obtained from the catalogs available at VizieR. All the pairs fulfill the Halbwachs criteria, employed to increase the probability of a physical bond between the two components.

## Method

In previous papers such as Greaves (2004), new common proper-motion pairs (CPMPs in the rest of the paper) have been obtained from different astronomy catalogs available at VizieR. It was observed that in many cases the data obtained from the catalogs were not reliable, and therefore a final phase checking the existence of some image in Aladin (Bonnarel, et al., 2000) confirming the pairs data was requested.

## Results

Table 1 shows the final list of 37 CPMP was obtained. For each pair we include:

The coordinates of the primary in the catalog.
The components, marked as AB in all the cases.
The visual magnitude V for both components.
The source of these data is shown in the two first characters of column 'Source'.

The epoch and astrometry data of the pair: position angle and separation. In all the cases the data have been obtain from the 2MASS catalog. The astrometry data was obtained from the coordinates in decimal format following Sinnott (1984). The separation is given in seconds and the position angle in degrees.

Columns 'PM RA' and 'PM DEC 'shows the proper movement of the two components in milliarcsecond/ year. The source of these data is shown in the last two characters of column 'Source'.

Finally column 'Notes' indicates the special situations.

## Conclusions

Although many of the papers on new pairs follow the approach of first using the data catalogs and then checking the images, the converse procedure is also fruitful. This is the case for those pairs whose proper motion data, used to filter line-of-sight pairs, are obtained in different catalogs. The result is the list of 37 new CPMPs presented in this paper.

## Acknowledgements

This research makes use of the ALADIN Interactive Sky Atlas and of the VizieR database of astronomical catalogues, all maintained at the Centre de Données Astronomiques, Strasbourg, France, and of the data products from the Two Micron All Sky Survey (2MASS), which is a joint project of the University of Massachusetts.

#### Abstract

As part of the Mt. Wilson Double Star Workshop, the authors used a double image micrometer to observe two double stars, STF2383CD and STF2583AB, on the night of July 19, 2013 (B2013.547). The instrument was designed in 1949 by Bernard Lyot and built by Meca-Precis. We found separations of $2.53 \pm 0.29^{\prime \prime}$ for STF2383CD and $1.58 \pm 0.40$ " for STF2583AB, and positions angles of $77.8 \pm 2.3^{\circ}$ for STF 2383 CD and $103.4 \pm 1.6^{\circ}$ for STF2583AB. The scarcity of double image micrometers and the opportunity to use the historic 60 inch telescope at Mt Wilson made this workshop a very unique experience.

## Introduction

The Mount Wilson Double Star Workshop was held to bring together double star enthusiasts at one of the cathedrals of astronomy, the historic and hallowed site where great discoveries about the universe have been made. To do research in a place covered by the footprints of great men such as Albert Michelson, Milton Humason, George Hale, Edwin Hubble, and Albert Einstein is a dream come true for many scientists. Our brief stint as researchers at Mount Wilson was a half night of observations on Friday July 19, 2013, and two days of data analysis and paper writing in the historic Mt Wilson Library.

We used the 60 inch telescope that Edwin Hubble was groomed on before using the 100 inch Hooker telescope. Thomas Barnes, the grandfather of one of our team members, Cheryl Genet, was the foreman for the construction of the 60 inch telescope, and ground the mirror with George Ritche. Merritt Dowd, Thomas Barnes's brother-in-law and the Chief Electrician at Mt Wilson, and Catherine Dowd Barnes, Thomas Barnes's wife, stayed on Mt Wilson during the entire construction of the 60 inch observatory. To the three generations of descendants of Thomas and Catherine Barnes who were present at the workshop (Cheryl Genet, John Davidson, and Noah and Adam Tassell), this was much

Figure 1. The participants of the Mt Wilson Double Star Workshop pose in front of the 100 inch Hooker telescope. In order from left to right: (Standing) Rick Wasson, Mark Brewer, Reed Estrada, Cheryl Genet, Russ Genet, Adam Tassell, Noah Tassell, Joseph Carro, Inga Kenney, and Ryan Gelston. (Sitting and Kneeling) Vera Wallen, Rafael Ramos, John Davidson, Eric Weise, Cassie Hollman, and Chris Estrada.
more than a scientific endeavor.
Our observing session started with a spectacular viewing of Saturn with a visual eyepiece. The seeing was extraordinary, less than half of an arc second. The

## Mt. Wilson Meets the Lyot Double Image Micrometer

Figure 2. Christine Gerhart, who also worked for the observatory as a telescope operator, making a measurement with the Lyot dou-ble-image micrometer.
image of the planet was incredibly crisp and detailed. Even the various longitudinal strata of swirling gas were visible and appeared like layers of a cake. After this "Oh, ah" session, our scientific observations began. The first two hours were devoted to an astrometric eyepiece, while the second two hours were given to the double image micrometer.

## Historical Perspective

## The Double Image Micrometer

The concept of doubling the image of an astronomical object for the purpose of angular measurements has been known for some time. Ole Römer suggested this method in 1675 (Lord 1994-B), although the technique was not put into practice for three quarters of a century. Some of the first known descriptions of such a device were given by Servington Savery in 1743 (Short 1753) and John Dolland (1953). Many adaptations were made to these early designs by George Airy (1845), Simms (1858), and others.

A double image micrometer works by creating two images of an object that are, for all intents and purposes, identical. If an observer can put the two images (i.e. images of a planet) into a certain configuration (i.e. such that the images of the planets are touching), then one can calculate the angular separation between the two images. Figure 3 shows this arrangement. These micrometers have been used to measure an assortment of stellar objects, including the diameters of planets, the phases of the sun and moon during partial eclipses, and, of course, the separation of double stars. These early devices, however, do not even remotely resemble the most recent double image micrometer. Dolland's and Airy's double image micrometers were of a subclass called the

Figure 3. When two images of a planet are arranged as seen using a double image micrometer, the angular diameter of the planet ( $\rho$ ) is equal to the artificial separation of the two images (d) created by the instrument.
"divided lens" micrometer, and consisted of four lenses, one of which was split along its diameter (Lord 2012). These predecessors to the modern version were all notorious for lengthy calibration procedures and chromatic aberrations to varying degrees (Lohse 1902).

In 1949, French astronomers Bernard Lyot and Henri Camichel patented a double image micrometer that used calcite as a means of producing two images of stellar objects. The birefringent properties of calcite mean that two images can be made by one crystal "Spar plate" and an eyepiece, rather than a divided lens and multiple focusing lenses. This improvement single-handedly eliminated the long calibration procedures and the chromatic aberrations that plagued this instrument's predecessors. Lyot contracted the company Meca-Precis to construct his micrometer, although only a handful of the lavishly expensive, yet beautifully simplistic instruments were built. The particular micrometer we used in this paper is serial number 10. In tribute to its innovator we fondly call our micrometer "the Lyot".

## The 60 Inch Telescope

George Ellery Hale was a prolific scientific organizer. He was the driving force behind the establishment of four of the world's largest telescopes: the Yerkes 40 inch (completed in 1887), the Mt Wilson 60 inch (first light in 1908), the Mt Wilson 100 inch "Hooker" telescope (first light in 1917), and the Palomar 200 inch "Hale" telescope that was completed after his death (first light in 1949). He also co-founded the California Institute of Technology-Cal Tech (1891). When he decided to build the 60 inch telescope on Mt Wilson, he

Mt. Wilson Meets the Lyot Double Image Micrometer

Figure 4. When an object is viewed through a calcite prism, two images are seen. The distance between these two images is a function of the angle at which the observer sits. If the observer places his eye on the line orthogonal to the surface of this crystal, only one image of "Double Refraction" will be seen.
chose this location for its excellent seeing. The peak stands in the Los Angeles National Forest at 5713 feet above sea level, just a 25 mile drive (or buggy ride in those days) away from Cal Tech. The blank for the 60 inch mirror was donated in 1896 and was ground by George Ritchey and his right hand man Thomas Barnes, Cheryl Genet's grandfather. During the first light ceremony of the telescope, Thomas and Catherine Barnes, their son Frederick, and Merritt Dowd were present; the only known first-hand account of the event is contained in a diary written by Catherine Barnes. This diary is in the possession of John Davidson, Cheryl Genet's son, and was exhibited at the workshop.

The time the 60 inch spent as the world's largest active telescope was short. In 1906, two years before first light on the 60 inch, Hale ordered the casting of the mirror blank for the 100 inch Hooker telescope. In 1917, after spending only nine years as the world's largest telescope, the 60 inch was surpassed in size by its big sister. In 1986, 37 years after Bernard Lyot invented his double image micrometer, the Mt Wilson Institute took over operation of the observatory (http:// www.mtwilson.edu/cent.php). This time-line, and the scarcity of Lyot's micrometer, leads us to believe that our observation with his double image micrometer was the first time in the history of the 60 inch that one of these instruments was used.

## Methods

The methods employed by the authors as well as detailed operations of the Lyot can be found in Lord (1994-A).

The Lyot micrometer is a double-image micrometer,

Figure 5. Principle of operation of Lyot double-image micrometer
implemented by a prism of calcite crystal, which is birefringent, meaning it has two indices of refraction. The "Spath blade," which holds the calcite crystal, is located just before the telescope focus, and is followed by a reticle eyepiece with which the operator views the image plane. The micrometer has two vernier dials that enable precise rotation of the calcite Spath blade, as well as rotation of the entire instrument around the optical axis. An example of the refractive properties of a calcite crystal is shown in Figure 4.

If a single star is viewed, the calcite Spath blade places two images at the image plane (Figure 5). The two images are the "ordinary" and "extraordinary" refracted rays of the incoming starlight. The angular separation between these two images is a function of the "inclination angle" of the calcite crystal with respect to the incident light path. When the face of the calcite prism is normal to the light of the star, the ordinary and extraordinary images coincide. When the plate is rotated, the " 0 " and "e" images separate; greater inclination of the Spath blade provides wider separation of the " 0 " and "e" images. These two images have perpendicular polarizations, but they are indistinguishable to the visual observer. When a double star is viewed through an inclined Spath blade, a total of four star images are visible -two of the primary member and two of the secondary member of the pair.

The other alignment configuration we used strives to place the four star images into a perfect square (following a procedure similar to the one described in the previous paragraph). Again, the human eye is remarkably adept at detecting very slight asymmetries in such a pattern, which enables the observer to achieve excellent alignment and measurement of the pattern. The

## Mt. Wilson Meets the Lyot Double Image Micrometer

Figure 6. Lyot instrument provides two adjustments of the image: tilting the Spath blade changes the separation of the " $o$ " and " $e$ " images, and rotating the instrument around the optical axis causes the " $e$ " images to nutate around the " $o$ " images. It is also possible to arrange the star images in a line such that $\rho$ is half of the image separation.
interpretation of separation (vs. Spath blade tilt) is iden- was required; the scale factor is provided by the manutical to the equidistant-linear alignment pattern, but the facturer's calibration curve for the "angular distance interpretation of the position angle (vs. instrument rota- factor" in addition to the focal length of the telescope. tion angle around the optical axis) is 90 (or 270) degrees Our limited experimentation with this device indicates different from the linear pattern. Thus it is important to that the manufacturer's calibration is still very good, and record in the observer's notes which pattern was used!

Our observation method incorporated an "adjust and confirm" approach to achieving the desired alignment of the pattern. The first observer adjusted the tilt and rotation to create the desired equidistant-linear pattern, and then the second observer examined the image to confirm the pattern. The tilt and rotation were then recorded. The Spath blade was then tilted in the opposite direction, the star pattern adjusted, and a second observer confirmed the pattern before the tilt and rotation orientations were the recorded. The use of both "positive" and "negative" tilt directions of the Spath blade turned out to be valuable because it highlighted a small but significant zero-point offset in the readings of the tilt orientation of the Spath blade.

One of the features of the Lyot instrument is that reading the star-image orientation does not depend on an illuminated reticle. This avoids the potential glare from the reticle interfere with observation of the target pair (or reading of the reticle); and it eliminates the need for achieving focus on both the reticle and the target stars. The absence of the illuminated reticle makes the colors of the stars delightfully apparent: one of our pairs presented a pretty contrast between its gold and the white components.

No calibration of the Spath blade tilt angle reading
is applicable when the precise focal length of the telescope is known. However, we will remain diligent to conduct observation/measurement of well-attested pairs as a way of confirming the validity of the tilt calibration.

The rotational alignment is calibrated using a singleline reticle. The observer selects a single star, places it on this reticle line, turns off the telescope drive, and rotates the instrument so that the path of drift is collinear with the reticle. This rotation-orientation reading defines the E-W celestial axis and calibrates the position angle measurements. We found north to be at $3.16^{\circ}$ with respect to the position angle dial on the instrument. The standard deviation and standard error of the mean for north were $1.18^{\circ}$ and $0.42^{\circ}$, respectively.

## Data

Our data is presented below in Table 1, and is compared to past observations reported to the WDS in Table 2. A note on the standard deviation of the separation values: to find the separation of a system, the inclination, $i$, of the Spath blade is recorded, and the "Angular Distance Factor", $\varphi\left(\mathrm{i}^{\prime}\right)$, is used to convert this value into a separation in arc seconds.

## Mt. Wilson Meets the Lyot Double Image Micrometer

Table 1. Our Data. Epoch, B2013.547.

|  | STF 2383CD |  | STF 2583AB |  |
| :---: | :---: | :---: | :---: | :---: |
|  | PA | Sep. | PA | Sep. |
| Number of <br> Observations | 6 | 11 | 8 | 8 |
| Average | $77.8^{\circ}$ | $2.53^{\prime \prime}$ | $103.4^{\circ}$ | $1.58^{\prime \prime}$ |
| Standard Deviation | $5.6^{\circ}$ | $0.95^{\prime \prime}$ | $6.6^{\circ}$ | $1.12^{\prime \prime}$ |
| Standard Error of <br> the Mean | $2.3^{\circ}$ | $0.29^{\prime \prime}$ | $1.6^{\circ}$ | $0.40^{\prime \prime}$ |

The derivation of the formula $\varphi(i)$ is given by Lord (2012). Each measurement of the separation is converted to the image separation, $d$, by

$$
d=\frac{e}{F} \phi(i)
$$

where $e$ is the thickness of the Spath blade (we used the Meca-Precis stated value $e=4 \mathrm{~mm}$ ) and $F$ is the effective focal length of the telescope (in our case, $F=24 \mathrm{~m}$ ). The image separation, $d$, is related to the separation of the stars by a factor of $1 / 2,1$, or 2 , depending on how the two images of the binary stars were arranged during observations (see methods section). To find the standard deviations of our data, each observation was converted to a separation using the above formulas and then applying the standard formulas.

The position angle was obtained by reading the position angle dial on the instrument and applying our offset from the E-W celestial axis. Due to the zero point offset, our position angle measurements have a double peak distribution. Until we have more data to quantify this offset, we calculate the standard deviation of each of these peaks and then add these in quadrature:

$$
\sigma=\sqrt{\sigma_{A}^{2}+\sigma_{B}^{2}}
$$

During the observations of STF 2383CD the micrometer was twisted in the drawtube assembly. We had not taken any calibration measurements to establish the direction of North before this happened. Because of this, we lost five position angle measurements. To compensate, we made extra observations of this system. Thus we have a different number of position angle and separation measurements for STF 2383CD, measurements that are usually made concurrently.

Table 2. Past 10 observations from the WDS.

|  | STF 2383CD |  | STF 2583AB |  |
| :---: | :---: | :---: | :---: | :---: |
|  | PA | Sep. | PA | Sep. |
| WDS Average | $78.25^{\circ}$ | $2.294^{\prime \prime}$ | $105.04^{\circ}$ | $1.422^{\prime \prime}$ |
| WDS - Ours <br> ( $\Delta$ ) | $0.49^{\circ}$ | $-0.235^{\prime \prime}$ | $1.65^{\circ}$ | $-0.161^{\prime \prime}$ |
| \% Diff <br> ( /ours) | N/A | $9.3 \%$ | N/A | $10.2 \%$ |
| Our Standard <br> Deviation ( $\sigma)$ | $5.59^{\circ}$ | $0.948^{\prime \prime}$ | $6.63^{\circ}$ | $1.121^{\prime \prime}$ |
| $\Delta / \sigma$ | 0.088 | 0.248 | 0.249 | 0.144 |

## Analysis

To check the validity of our measurements, we compared our data to the average of the past ten observations reported to the Washington Double Star Catalog (WDS) (Mason and Hartkopf 2013). For the system STF 2383CD these observations were made between 2009.803 and 2012.628, and for the system STF 2583 AB these observations were made between 2008.560 and 2012.729. We show these averages in Table 2 .

We used three values to compare our data to the past observations. First we used the difference between our measurements and the average of the past ten observations $(\Delta)$. This value shows how much our value is over or under the past observations. Second, the Percent Difference shows how significant our under/overestimate is. Finally, we looked at how many standard deviations we were off from the past ten observations $(\Delta / \sigma)$.

For both target systems, our Position Angle data are in agreement with the past observations. Our separation data, on the other hand, are not. While the differences between our data and the past observations are less than one arc second, they are still significant compared to the separation of the systems, as evidenced by the Percent Difference values. One might comment that we should have observed wider pairs, but this is not possible, owing to the narrow field of view of the instrument. However, considering the time constraints and that the majority of observers were using the Lyot for the first time this night, we concluded that our observations were satisfactory.

## Acknowledgments

We are grateful to the Mt. Wilson Institute for the use of the famous 60 -inch telescope for our research, and for allowing us to use the historic library where we analyzed our data and wrote our papers. We are also thankful to Dave Jurasevich, then the Deputy Director for Operations at Mt Wilson, for an incredible and more

## Mt. Wilson Meets the Lyot Double Image Micrometer

than extensive tour of the facilities at Mt Wilson. Our Lord, C. J. R. 1994-B. History \& Development of the research made use of the Washington Double Star Catalog, maintained by Brian Mason and William Hartkopf at the United States Naval Observatory.

The Journal of Double Star Observations is an electronic journal published quarterly. Copies can be freely downloaded from http:/ /www.jdso.org.

No part of this issue may be sold or used in commercial products without written permission of the Journal of Double Star Observations.
©2015 Journal of Double Star Observations

Questions, comments, or submissions may be directed to rclark@southalabama.edu or to rmollise@bellsouth.net

The Journal of Double Star Observations (JDSO) publishes articles on any and all aspects of astronomy involving double and binary stars. The $J D S O$ is especially interested in observations made by amateur astronomers. Submitted articles announcing measurements, discoveries, or conclusions about double or binary stars may undergo a peer review. This means that a paper submitted by an amateur astronomer will be reviewed by other amateur astronomers doing similar work.

Not all articles will undergo a peer review. Articles that are of more general interest but that have little new scientific content such as articles generally describing double stars, observing sessions, star parties, etc. will not be refereed.

Submitted manuscripts must be original, unpublished material and written in English. They should contain an abstract and a short description or biography ( 2 or 3 sentences) of the author(s). For more information about format of submitted articles, please see our web site at http://www.jdso.org

Submissions should be made electronically via e-mail to rclark@southalabama.edu or to rmolise@bellsouth.net. Articles should be attached to the email in Microsoft Word, Word Perfect, Open Office, or text format. All images should be in jpg or fits format.

We're on the web!
