# Some 2015 Measurements of Wide and Faint Double Stars Compared with Visual Observations 

Wilfried R.A. Knapp<br>Vienna, Austria<br>wilfried.knapp@gmail.com

#### Abstract

A backlog of astrometry and photometry measurements made in 2015 for comparison with visual observations is reported here with the intention of providing recent precise measurements for the given objects

## Report

Visual observations often pose questions when comparing the impressions with the parameters listed in the Washington Double Star catalog and often questions arise during session planning. To countercheck such impressions, I made measurements based on images made with a remote telescope. In most cases the
measurement results confirmed the need for updating the current WDS catalog data, but in some cases the data made evident that visual impressions can sometimes be very misleading.

The WDS catalog data from the end of 2015 for the studied objects is listed in Table 1.

The measurement results are given in Table 2 with the Notes column providing additional information

Table 1: WDS catalog values for the selected objects intended for comparison with visual observation

## Some 2015 Measurements of Wide and Faint Double Stars Compared with Visual Observations

about the used images and references to visual observation. In Table 2 RA and Dec are the coordinates based on plate solving with UCAC4 reference stars in the 10.5 to 14.5 mag range. Sep is separation calculated as

$$
S e p=\sqrt{\left[\left(R A_{2}-R A_{1}\right) \cos \left(d e c_{1}\right)\right]^{2}+\left(\operatorname{dec}_{2}-\operatorname{dec}_{1}\right)^{2}}
$$

in radians. Err_Sep is calculated as

$$
E r r_{-} S e p=\sqrt{d R A^{2}+d D e c^{2}}
$$

with $d R A$ and $d D e c$ as average RA and Dec plate solving errors. PA is calculated as

$$
P A=\arctan \left[\frac{\left(R A_{2}-R A_{1}\right) \cos \left(D e c_{1}\right)}{D e c_{2}-D e c_{1}}\right]
$$

in radians depending on quadrant. Err_PA is the error estimation for PA calculated as

$$
E r r_{-} P A=\arctan \left(E r r_{-} S e p / S e p\right)
$$

in degrees assuming the worst case that Err_Sep points in the right angle to the direction of the separation means perpendicular to the separation vector.

Mag is the photometry result based on UCAC4 reference stars with Vmags between magnitudes 10.5 and 14.5. Results for stars significantly brighter than 10.5 mag are for this reason not reliable and therefore not listed. Err_Mag is calculated as

$$
E r r_{-} M a g=\sqrt{d V_{m a g}^{2}+\left[2.5 \log _{10}(1+1 / S N R)\right]^{2}}
$$

with dVmag as the average Vmag error over all used reference stars and SNR is the signal to noise ratio for the given star.

Date is the Bessel epoch in 2015 and N is the number of images (usually with one second exposure time) used for the reported values. iT in the Notes column indicates the telescope used with number of images and exposure time given.

## Telescope Magnitude Resolution Limit Determination

Additionally a few wide multiples (BU 298, BAR 1 and SMR 33) were used to determine the current telescope magnitude resolution limit for visual observation sessions. For this purpose images and measurements were made to simply provide reliable magnitudes.

The measurement results are given in Table 3 with the Notes column providing additional information about the used images and references to visual observation and current end of 2015 WDS catalog data. Column headings are the same as described above for the

Table 2 headings.
Specifications of the used iTelescope equipmentare as follows:
iT24: 610 mm CDK with 3962 mm focal length. CCD: FLI-PL09000. Resolution $0.62 \mathrm{arcsec} / \mathrm{pixel}$. Vfilter. No transformation coefficients available. Located in Auberry, California. Elevation 1405m

## Astrometry Quality Control:

A few of the listed objects were selected by random for the purpose of quality control by comparison with URAT1 coordinates (considered the currently most precise available even if preliminary) if available for both components with the results listed below in Table 4.

All checked astrometry results were within the given error range estimation confirmed by comparison with the URAT1 coordinates. Comparison of measured magnitudes with URAT Vmags were only possible for a smaller number of objects with several results outside the given error range estimation but only by a very small margin.

## Some 2015 Measurements of Wide and Faint Double Stars Compared with Visual Observations

Notes to Table 2.

1. iT24 stack 5x3s. SNR B<20. Visual observation suggested $B$ far fainter than 12.1 mag, confirmed
2. iT24 1x3s. Touching to overlapping star disks. Visual observation suggested $A$ and $B$ a tad brighter than listed, confirmed
3. iT24 stack $5 \times 3$ s. Visual observation suggested $B$ somewhat fainter, not confirmed by this measurement
4. iT24 stack 5x3s. Visual observation suggested B brighter than listed, confirmed
5. iT24 stack $5 \times 3$ s. Visual observation suggested C brighter than listed, confirmed
6. iT24 1x3s. SNR for $B<20$. Visual observation suggested B far fainter than 10mag (old WDS August 2013 value in my session plan, meanwhile corrected to estimated 12). But Sep and PA also quite different
7. iT24 1x3s. Zero digit WDS mag for C suggested check
8. iT24 1x3s. SNR for $B<20$. WDS mags of $12 / 12.4$ suggested check for good reason. No visual observation
9. iT24 1x3s. Visual observation suggested $C$ far brighter than 12.3 mag (old WDS August 2013 value in my session plan, meanwhile corrected to 11.56 confirmed by measurement)
10. iT24 1x3s. Visual observation suggested $B$ far fainter than 9.9 mag - not supported by this measurement but overlapping star disks might make B probably appear brighter than it really is
11. iT24 1x3s. Visual observation suggested $B$ a bit brighter than 11.3, confirmed
12. iT24 1x3s. Visual observation suggested $B$ fainter than 10.6 (WDS August 2013 value, meanwhile changed to 10.78), confirmed
13. iT24 1x3s. Visual observation suggested $A$ and $B$ far fainter than 9.4 mag, confirmed
14. iT24 1x3s. Single digit WDS magnitude for $B$ suggested check
15. iT24 1x3s. Touching star disks. Visual impression of $B$ being reddish and fainter than currently listed and also than measured here
16. iT24 1x3s. SNR for $B<20$. Visual observation suggests B a bit fainter than 11.3mag, confirmed
17. iT24 stack 5x3s. Visual observation suggested B being fainter than 11.86 mag - not really confirmed by this measurement, may be a tad
18. iT24 1x3s. SNR for $B<20$. Single digit WDS magnitude for B suggested a check
19. iT24 stack 5x3s. Visual observation suggested A much fainter than WDS 10.7mag. Confirmed by measurement
20. iT24 stack $5 \times 3$ s. Visual impression $A$ and $B$ a tad brighter than WDS listed, confirmed
21. iT24 stack $5 \times 3$ s. Heavily overlapping star disks - so this measurement is not very reliable. But the visual impression that this double is far fainter than WDS $9.2 / 9.7 \mathrm{mag}$ is certainly confirmed
22. iT24 1x3s. Visual observation suggested $B$ being fainter than WDS 10.5 confirmed by measurement
23. iT24 1x3s. Visual observation suggested $A$ and $B$ being far fainter than WDS 9.2/9.6, confirmed
24. iT24 1x3s. Single digit WDS 11.9 mag suggested check
25. iT24 1x3s. Visual observation suggested $D$ being brighter than WDS 10.56 mag , but this was not confirmed
26. iT24 1x3s. Part of STF 2225. WDS data confirmed
27. iT24 1x3s. Visual observation suggested $B$ being fainter than WDS 11.1mag, confirmed

Some 2015 Measurements of Wide and Faint Double Stars Compared with Visual Observations

## Some 2015 Measurements of Wide and Faint Double Stars Compared with Visual Observations

Notes to Table 3.

1. iT24 1x3s image taken for TML check. Sep and PA according to WDS values, Mag B about 0.3 mag fainter than WDS listed
2. iT24 1x3s image taken for TML check. Part of BU298. Visual observation suggested C fainter than listed, not confirmed
3. iT24 1x3s image taken for TML check. Sep and PA according to WDS values, Mag D about 0.4 mag brighter than listed
4. iT24 1x3s image taken for TML check. Sep and PA according to WDS values, Mag E about 0.9 mag fainter than listed
5. iT24 1x3s image taken for TML check. Sep and PA according to WDS values, Mag F about 1.1 mag fainter than listed
6. iT24 1x3s taken for TML check. SNR for $\mathrm{C}<20$. C about 0.3 mag fainter than listed
7. iT24 1x3s taken for TML check. WDS mag for $D$ about confirmed
8. iT24 1x3s taken for TML check. WDS mag for E confirmed
9. iT24 1x3s taken for TML check. WDS mag for $F$ confirmed
10. iT24 $1 \times 3$ s taken for TML check. G about 0.3 mag fainter than listed
11. iT24 1x3s taken for TML check. C about 0.3mag fainter than listed
12. iT24 1x3s taken for TML check. WDS mag for I about confirmed
13. iT24 stack $5 \times 3$ s taken for TML check. P about 0.5 mag fainter than listed
14. iT24 stack $5 \times 3$ s taken for TML check. $Q$ about 1.4mag fainter than listed
15. iT24 stack $5 \times 3$ s taken for TML check. $R$ about 1.2mag fainter than listed
16. iT24 stack $5 \times 3$ s taken for TML check. T about 0.3 mag fainter than listed

# Visual Observation and Measurements of Some Tycho Double Stars 

Wilfried R.A. Knapp<br>Vienna, Austria<br>wilfried.knapp@gmail.com<br>Ross Gould<br>Double Star Notes, Australian Sky \& Telescope<br>Canberra, ACT, Australia<br>rgould1792@optusnet.com.au

#### Abstract

No humble human visual observer would dare to challenge a robotic telescope - yet many Tycho based results are highly questionable to utterly wrong as is shown on several examples.

## 1. Introduction

Several years ago I observed mostly STF doubles as these objects have a record with many observations, are well documented, and reasonable targets for small amateur telescopes. Session planning based on the current WDS catalog data at the time of the observations assumed that recent measurements would provide most precise data. One of the selected objects was STF442, with 2.5 " separation and magnitudes 10.06 and 13.0 (WDS values per end of 2014) - obviously not suited for a 120 mm refractor, so it took me some time to give it a try in a night with excellent seeing. To my surprise resolution was easy and both components were rather equal bright. I checked then the STF catalog directly and found that F . Struve estimated the components had magnitudes 9.9 and 10.4. I then contacted Brian Mason at the USNO and it was determined that the 13 magnitude for the companion was based on Tycho, but obviously wrong, and the WDS catalog entry was accordingly changed to 10.5 magnitude for the secondary to keep the original $\Delta \mathrm{m}$. This was my first experience with incorrect Tycho data; anecdotal evidence and no reason for a follow up.

But recently I selected objects from the WDS cata$\log$ double stars suited for observation with telescopes in the 150 to 200 mm aperture range in Cygnus. This resulted in several hundred doubles with different discoverer designations, but a good part were TDS and

TDT objects in the range of 1.5 to 2.5 " separation and brightness in the 11 to 12 magnitude range. First, visual observation results were not very convincing, so I checked the data on these objects in more detail. I noticed for the first time that most of these objects showed only one first/last observation indicating that Tycho was not only the "discoverer" of these doubles, but that so far no other observations were available to confirm these "discoveries".

I then checked directly the Tycho Double Star cata$\log$ and found about 98,000 objects meaning about 49,000 doubles as all components were listed separately. About $80 \%$ of these objects show a WDS ID indicating that they are included in the WDS catalog, but mostly with well-known discoverer designations. Why the rest is not included in the WDS catalog is not entirely clear to me, but I assume the data for these objects is suspect from the first impression.

I then checked the WDS catalog and found about 9,800 objects with a TDS designation and about 4,200 objects with a TDT designation, so we have in total about 14,000 WDS objects with Tycho as discoverer (most or all of them obviously based on the report of Fabricius et al., 2002) As mentioned before, most of them are without a confirming second observation. The vast majority of these objects are in the range of less than 1" separation with quite faint components. So they are not really suited for visual amateur observation and certainly also quite difficult for imaging unless perhaps

## Visual Observation and Measurements of Some Tycho Double Stars

with speckle interferometry. From the less than 3000 TDS objects with separation 1.5 " or larger only about 600 show at least a second confirming observation and about 200 are listed with " X " in the notes section marking bogus doubles giving a ratio from 3:1 for confirmations against bogus.

I then selected a few of TDS and TDT objects in Cygnus in the 1.5 " or larger separation range with only one observation to give it a try with the best suited iTelescope equipment available to me. Images with 3 second exposure time taken with remote telescope iT24 (for specifications see Acknowledgements) should, according to my experience, provide at least significant elongations if not clear separation of such objects, depending on the magnitudes of the components. Table 1 lists the WDS values for these selected objects.

## 2. Further Research

One image was taken for the selected objects with iT24 with 3 s exposure time; at least this was the intention, because the weather did not cooperate for an extended period, I missed several of the planned objects. The conditions for visual observations were even worse so that I managed this for only a small part of the list. The images I got were initially plate solved with AAVSO VPhot and then processed with Astrometrica with the results given in Table 2 with missed objects not listed.

In the Table 2 headings, "M1(2) new" means photometry result with V-filter for primary and secondary;

$$
\operatorname{ErrM} 1(2)=\sqrt{d V_{m a g}^{2}+\operatorname{Err}(S N R)^{2}}
$$

"Err M1(2)" stands for the calculated error estimation where dVmag is the average magnitude error from plate solving and SNR is the signal to noise ratio (not reported here). Date is Bessel epoch of observation.

## Counter Check

As these results with only one confirmation out of (not counting the one declared bogus) 16 measured objects were not positive, I decided to have a look at Tycho doubles in another constellation high in altitude from a location in Australia. This allowed me to use the iTelescope iT27 with a somewhat better 0.53 "/pixel resolution in Siding Spring and to invite Ross Gould to contribute visual observations. The obvious choice was the constellation Phoenix with the unconfirmed TDS/ TDT objects selected by separation larger than 1.5 arcseconds (including RST38 suggested by Ross as reference object with similar data but several confirming observations) shown in Table 3.

Table 1: WDS values per beginning of 2016 for the selected unconfirmed TDS/TDT objects in Cygnus with separation larger than 1.5 arcseconds

## Visual Observation and Measurements of Some Tycho Double Stars

## (Continued from page 428)

## Photometry and Astrometry in Phoenix

For each selected object, one 3 s image was taken with iT27 and, after the initial plate solving with AAVSO, was VPhot processed with Astrometrica. With the exception of TDT4192 all results listed in Table 4 were instantly obvious. Ross had bad luck with the weather making conclusive visual observation results impossible so we got here only a few hints (see Notes column).

Astrometry results are based on the formulae provided by R. Buchheim (2008) for calculating Sep and PA. Sep is separation and is calculated as

$$
\text { Sep }=\sqrt{\left[\left(R A_{2}-R A_{1}\right) \cos (D e c 1)\right]^{2}+\left(D e c_{2}-D e c_{1}\right)^{2}}
$$

in radians. Err Sep is the error estimation for Sep calculated as

$$
\text { Err Sep }=\sqrt{d R A^{2}+d D e c^{2}}
$$

ErrMag is the error estimation for Vmag results calculated as

$$
E r r M a g=\sqrt{d V_{m a g}^{2}+E r r S N R^{2}}
$$

Figure 1. Images of three measured doubles.
with Err_SNR calculated as $2.5 * \log _{10}(1+1 / \mathrm{SNR})$. PA is calculated as

$$
P A=\arctan \left[\frac{\left(R A_{2}-R A_{1}\right) \cos \left(D e c_{1}\right)}{D e c_{2}-D e c_{1}}\right]
$$

in radians and Err_PA is the error estimation for PA calculated as arctan(Err_Sep/Sep) in degrees, assuming the worst case that dSep points in the right angle to the direction of the separation means perpendicular to the separation vector

Just for visual comparison, Figure 1 shows three images side by side.

## Additional Research

This again rather meager result in terms of confirming WDS Tycho Double Stars with only 1 positive
(Continued on page 433)

2. iT27 1x3s. No resolution, not even a hint for an elongation. Bogus assumed
3. iT27 1x3s. Overlapping star disks, clear elongation. Confirmed
4. iT27 1x3s. Overlapping star disks, clear elongation. Confirmed. $A$ and $B$ seem equally bright
5. iT27 1x3s. No resolution, not even a hint for an elongation. Same result with a second image. Bogus assumed

## Visual Observation and Measurements of Some Tycho Double Stars

out of 14 objects called for just another attempt for a counter check. Beginning of 2016 the constellation For was reasonably high for imaging from Australia so just another set of images with the same selection criterion separation 1.5 " or larger was taken with the following results in Table 5. Table headings in Table 5 were calculated as described for Table 4 earlier in this article.

## Additional Research

With 2 confirmations out of 12 objects the wider TDS objects in Fornax fared a bit better than in Cygnus and Phoenix. To eliminate all potential doubts in terms of image resolution, I decided to have a look at objects far beyond any such questions in Puppis with 9 already confirmed objects with a separation of at least 2.6 arcseconds.

All these objects were confirmed again with our own measurements. Sep and PA in most cases were within the given error range compared with the values listed in the WDS catalog (in two cases with change of the components A and B according to the magnitude measurement). For the few cases outside the error range a counter check with URAT1 would be helpful for detecting potential proper motion issues, but URAT1 is currently not available for the southern sky.

Surprisingly all of the selected unconfirmed objects with rather comfortable separation have to be assumed bogus. To visualize these results some cut outs from the center of the used images are given in Figure 2.

## Closing the Circle

In the final stage of writing this report I got the hint

Figure 3. Image examples for the selected TDS objects in Pup showing confirmed objects versus obvious bogus

## Visual Observation and Measurements of Some Tycho Double Stars

Table 6. Measurement Results for HJ348

| Name |  | RA |  |  | Dec |  |  | Sep | Err Sep | PA | Err PA | Vmag | Err Vmag | Date |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| HJ348 | A | 04 | 43 | 04.967 | 33 | 55 | 47.08 | 30.262 | 0.318 | 285.329 | 0.603 | 7.315 | 0.140 | 2016.085 |
|  | B | 04 | 43 | 02.622 |  | 55 | 55.08 |  |  |  |  | 11.360 | 0.149 |  |

that HJ348 (WDS04431+3356 with Sep 30.6" $+7.42 / 9.5 \mathrm{mag} 286^{\circ} \mathrm{PA}$ ) in Auriga might be listed with a far too bright magnitude for the companion. Measurements based on a stack of $6 \times 1$ s images taken with iT18 resulted in the following values given in Table 6. This means that the companion is nearly 2 magnitudes fainter than currently listed in the WDS catalog. Checking HJ348 for synonyms I found that this pair is also included in the Tycho Double Star catalog being the source of the wrong magnitude for the companion similar situation to STF442.

## Historical Background to the Tycho Double Star Catalog (by Ross Gould)

The ESA Hipparcos satellite included the Tycho star mapper, which produced a catalogue of single stars, initially (Tycho-I) including just over 1 million stars to magnitude 11.5 , with positional and photometric data. The material was re-processed later to yield the Tycho-II catalogue of 2.5 million stars. From this, an initial analysis for double stars produced over 12,000 double star measures including 1234 new double star systems (Mason et al, AJ, 2000 December). Following this, a "dedicated re-reduction of the Tycho data" produced a total of 13,251 discoveries (Hoeg, Fabricius, et al, A\&A, 2002 March).

When the Hipparcos double star data had been released effort was made to confirm a good number of the claimed new pairs. This was done by speckle interferometry, these days a 'gold standard' for measures of doubles. Papers by Mason et al in 1999 and 2001 detailed this work (Mason et al, AJ 1999 and 2001). The conclusion, based on "only a subset of the new doubles" was that "most new Hipparcos doubles are bona fide double stars...", despite problems with verification of some of the list, using the McDonald Observatory 2.1metre telescope.

Fast forward a short time, and the new and greatly expanded Tycho Double Star Catalogue is announced, with over ten times as many new doubles as its predecessor, 13,251. The Fabricius 2002 paper provides details of the new analysis. Most of the added objects compared to the first catalogue "have separations between 0.3 and 1.0 arcsec".

The doubles were generated from single star results
in combination. Proximity of positions was the criterion, and the separation and angle were calculated from the relative positions. Delta-m was typically no more than 2. Various methods were used in attempting to eliminate spurious detections. There was acknowledgement that the new analysis involved the risk of more spurious detections or of errors in rho and theta.

Because of the generally dim magnitudes of the stars, mostly of 11th and 12th magnitude, these are not easy pairs for re-observing to confirm their reality. Thus, a suggestion made in the Mason 2001 Hipparcos paper was useful, that is, using CCD imaging, as the Tycho doubles are not so close as to require interferometry on large telescopes. That the dim magnitudes are bordering on the practical limits for speckle work, regardless of aperture, also recommends imaging as the best technique. Mason (1999) noted that telescopes larger than the USNO 26 -inch $(0.7 \mathrm{~m})$ refractor did little to increase the magnitude limit but instead reached the same signal-to-noise ratio in less time. Other changes, such as longer exposures, broader waveband filters, or less magnification resulting in less resolution, were unhelpful.

The sheer number of objects listed in the Tycho Double Star Catalogue appears to have discouraged extensive follow-ups on these objects. There are many non-Tycho recorded doubles that are brighter and will therefore attract attention first. Despite the extended TDS Catalogue being available in 2002, the great majority of objects in it have not as yet been confirmed. As of January 2016, Dr. Brian Mason/USNO said that from the total of 14,175 TDS and TDT pairs, 226 appear to be not real, 965 have been confirmed by something other than Hipparcos, and 12,984 are still of unconfirmed status.

The work recorded in the present paper, on some of the easier because wider Tycho doubles, has a much higher rate of bogus doubles than the above numbers. The objects assessed here were chosen from those with only a 1991 observation merely by their separation. Because these are the wider pairs, and much wider than the nominal resolution of Tycho - $0.8^{\prime \prime}$ - it is surprising that so few appear to match the Tycho data. A high proportion appear to be bogus doubles in this modest sample. Ongoing work will indicate how representative

## Visual Observation and Measurements of Some Tycho Double Stars

this sample is, at least for separations above 1.5 arcseconds. The many Tycho doubles that are closer will require for their verification more resolution capability than was used for this study.

## Summary

The results based on image processing and a few visual observations show a not positive record for the validity of the WDS catalog data for non-confirmed Tycho Double Stars - less than $10 \%$ of the by random selected TDS/TDT objects with separation larger than 1.5 arcseconds were confirmed as double stars and the rest was assumed being bogus without a regular pattern as for example a bright star nearby as is sometimes discussed. There seems to be no reason to consider the huge number of such objects with smaller separation being more reliable. This means that any TDS/TDT object with so far no confirming additional observation is to be considered with a rather high probability as potential bogus and that objects with other designations with Tycho based magnitudes might be better checked for the validity of at least the magnitude of the companion.

## Potential further research

Besides continuing to observe and image TDS objects wide enough to be resolved with the given equipment it might be of interest to image also rather close pairs for measurement of the combined magnitude and to compare this value with the calculated combined magnitude based on the current WDS catalog data crass differences here should indicate questionable objects. Ross is also working on checking wide TDS objects with Sky Survey images as at least a distinctive elongation is to be expected here for existing pairs.

# Double Star Observations with a 150mm Refractor in 2015 

Marc Oliver Maiwald<br>Witten, Germany<br>oliver-maiwald@web.de

#### Abstract

I present 136 measurements of 69 pairs made in 2015. For 26 stars, residuals were calculated.

In 2015 the same telescope and observing techniques as in previous years were used (Maiwald, 2013; Maiwald, 2014; Maiwald, 2015), with the only exception of a Alccd QHY 5-II camera with 3.75 mm pixels aquired in autumn 2015 and used for 9 observations in autumn and winter. For one observation a Philips SPC 900 NC was used. All other observations were made with an Imaging Source DMK 21 camera.

The imaging scales for the different optical setups are:

- DMK 21 at direct focus (f): 0.384 a.s. per pixel.
- DMK 21 with teleconverter 1.4x (TK 1.4): 0.297322 a.s. per pixel
- DMK 21 with teleconverter 2x (TK 2): 0.19876 a.s. per pixel
- QHY 5 - II at direct focus (f; A) : 0.25739 a.s. per pixel
- QHY 5 - II with teleconverter 1.4 (TK1.4; A): 0.1851 a.s. per pixel
- SPC 900 NC with teleconverter 2x (TK2; NC): 0.2091 a.s. per pixel

Notes to Table 2

1. Measurements for previous years in (Maiwald, 2014, p. 107). (Argyle, 2015, p.4) gives $\Delta \theta+1,6$ and $\Delta \rho+0,03$ for 2014.222 against the 2006 orbit.
2. My own measurements for previous years in (Maiwald, 2014, p. 191) and (Maiwald, 2015, p. 106). (Courtot, 2015, p. 11): $\Delta \theta-5,2$ and $\Delta \rho+0,09$ for 2014,290. $\Delta \theta$ always negative.
3. (Maiwald, 2014, p.190): $\Delta \theta-2,4$ and $\Delta \rho-0,13$ for 2013,3. (Argyle, 2012, p.4): $\Delta \theta-2,1$ and $\Delta \rho-0,08$ for 2011.360.
4. I was very surprised that this star could be measured with my telescope. Obviously the seeing was very good at these two evenings. My measurements for 2009 to 2014 in (Maiwald, 2014, p.191) and (Maiwald, 2015, p.106).
5. Star is known for deviation from ephemeris. See (Maiwald, 2014, p.190) and (Maiwald, 2015, p. 106) for my measurements from 2013 and 2014.
6. My own measurements show positive residuals in $\theta$ from 2012.6 to 2014.5. (Courtot, 2015, p.11): $\Delta \theta+1,4$ for 2014.694; (Argyle, 2013, p.4): $\Delta \theta+4,4$ for 2012,683.
7. Star is known for deviation from ephemeris. Residuals in $\theta$ always negative.

# Double Star Measurements Using a Webcam and DSLR, Annual Report of 2015 

Joerg S. Schlimmer<br>Seeheim-Jugenheim, Germany<br>js@epsilon-lyrae.de

#### Abstract

This paper reports 149 double star measurements from 2015; minimum separation is 0.58 as (eta CrB ), maximum separation is 447 as (BUP 153 AC ). The mean value of all measurements is 37.5 as.

## Report

This is a report of 149 double star measurements from 2015 made with a 12 -inch Newtonian telescope, a standard webcam, and in some cases also with a DSLR camera. The closest binary which could be measured was $\eta$ Coronae Borealis with a separation of 0.58 as, the maximum separation measured was on BUP 153 AC at 447 as. The mean value of all the measurements is 37.5 as. Figure 1 gives a more details about the statistics.

Measurements were done with a 12 -inch Newtonian telescope. This telescope has been used since 2012. A detailed description of the optical setup is given in annual report of 2012 (Schlimmer, 2013). Reproduction scales are about $0.77 \mathrm{as} /$ pixel in primary focus,
$0.34 \mathrm{as} /$ pixel with a 2 X barlow lens, $0.14 \mathrm{as} /$ pixel with a 5 X barlow lens for webcam measurements, and 0.70 as/pixel for DSLR images. In the case of DSLR imaging, an additional coma corrector was used. In all cases the data analyses were done with REDUC software (Florent Losse).

The focus of observations in the first half of 2015 was stars in Max Wolf's "Catalog About 1053 High Proper Motion Fix Stars" (Wolf, 1919), which are already listed in Simbad Database as well as in WDS catalog. This observational project was started in 2014 (Schlimmer, 2014).

In the second half of 2015, observations of close double stars gained more priority. The intention was to find out the limit of the observation site and instrumental conditions. Because the observation site is located

# New Companions to Double Star HJ 691 = WDS $05052+0914$ = HD 240582 

Wolfgang Vollman<br>Dammaeckergasse 28/D1/20, A-1210 Wien, Austria vollman@gmax.at

#### Abstract

This paper has measurements of new companions to the double star HJ 691 in Orion. One of the new companions is close enough to suspect it is a physical binary.

While measuring the double star HJ 691 in Orion (see Table 1) with the currently known companion in WDS [1] labeled as C , an additional close companion labeled B was noted. Two other previously uncataloged companions labeled D and E were also measured.

At the time of writing (Feb.2016) the data (eg. proper motion) in the various catalogs accessible via the Vizier service [3] are not able to indicate if A-B is a physical or optical pair. For B there seems to be no
catalog data available yet. The A-B pair is closer than the Aitken criterion [4], therefore we could suspect that it is a physical binary.

# Mind the Gap - Jonckheere Double Stars Not Listed in the WDS 

John Nanson<br>Star Splitters Double Star Blog<br>Manzanita, Oregon<br>inanson@nehalemtel.net<br>Wilfried R.A. Knapp<br>Vienna, Austria<br>wilfried.knapp@gmail.com

#### Abstract

We describe our efforts to determine the cross-referenced identifications of a large group of Robert Jonckheere's double stars which failed to turn up in a search of the WDS catalog sorted by discoverer ID.

## Report

During a review of the 3350 objects in Robert Jonckheere's 1962 Double Star Catalog (Catalogue Général de 3350 étoiles doubles de faible éclat observées de 1906 à 1962), we came across a reference in Amosse 2012 (p. 5) which described J 3319 as misidentified. In the course of determining the identity of that star, we discovered a total of 393 J objects which are not listed in the Washington Double Star Catalog, which results in a large gap in Jonckheere's total catalog of double stars. We soon discovered the WDS Notes Files contains references to most of these objects. Many of them have been cross-referenced with other identifications which have replaced the Jonckheere number in the WDS, primarily because those stars were discovered by other observers prior to the date of Jonckheere's discovery. Consequently, we downloaded the WDS Notes File into an Excel spreadsheet and searched for each of the objects in order to identify them. In the case of those objects for which we couldn't find references in the WDS Notes File, we used the Stelle Doppie web site (http://stelledoppie.goaction.it/) as a back-up source, which resulted in a small number of identifications.

In the course of that search, questions arose on two stars, J 1391, and J 3101. J 1391 is addressed in Table 3 and J 3101 is discussed in the next section of this paper.

At the conclusion of our searches, we were left with a list of 50 Jonckheere objects for which data or designations failed to turn up. To determine the identity of those objects, we turned to the pages of Robert Jonckheere's 1962 Catalog. After locating each entry, we examined it to see what clues were provided, entered his 2000 coordinates into Aladin, overlaid WDS identifications on the image, and confirmed the identities of all but a few of the objects. That information and the supporting data will be presented in a later supplement to this paper. Those objects are identified in the following table with the comment "No data found."

Also included in the list below are 23 objects which are listed in the WDS with no coordinates because they could not be located at or near the coordinates reported by Jonckheere. Bill Hartkopf at the USNO/WDS, who has determined the identities of many of Jonckheere's lost objects, has so far been unable to match up any of the 23 pairs. None of them have been declared bogus objects up to this point. We have an effort underway now to see if we can find at least some of this group.

## J 3101

It appears that Robert Jonckheere included J 3101 in his 1962 Catalogue Général solely because it's a red star. (He also included two other red stars in his cata$\log$, J 2001 and J 2011). As the excerpt from his cata$\log$ in Figure 1 shows, no measurements were made of J 3101. The text in the catalog entry reads: "Red star of

## Mind the Gap - Jonckheere Double Stars Not Listed in the WDS

Figure 1. Excerpt from Jonckheere's 1962 catalog.
magnitude 9.3, on February 16th, 1945, which is not included in the catalogues of F. Krueger and H. Schneller. BD +51606 (9,5), A.G. Leipzig II 9,0). On April 9 , 1945, a photo taken in full light by G. Guigay showed no traces of this star despite a one hour exposure."

As Figure 2 shows, there are actually two stars at the location of J 3101, which raises the question of why Jonckheere didn't refer to the pair as a double star and measure it. Equally puzzling is the reference in his 1962 catalog to the red star not being visible in a 1945 photograph. A search for the 1945 image failed to turn up anything, but in the process we confirmed the red star is designated a variable star by the AAVSO (Figure 3.) However, adding to the mystery is the AAVSO magnitude range of 9.1 to 10.5 , which would indicate

Figure 2. Aladin image showing Jonckheere's red star and the double star to the south of it. Neither J 3101 nor the white pair south of it was listed in the WDS when we began this paper. The red star is the one Jonckheere identified as J 3101, while the CCDM catalog refers to the white pair as CCDM 07156+0503 and identifies it as J 3101

## Mind the Gap - Jonckheere Double Stars Not Listed in the WDS

the star should have been visible in the 1945 photo.
Jonckheere also published an account of J 3101 in the March-April, 1945, issue of the Journal des Observateurs (Jonckheere 1945, p. 40) which went into more detail (Figure 4). In that short account, he describes J 3101 as a variable star, having found a magnitude of 9.5 for it in the Bonner Durchmusterung, as well as a magnitude for it of 9.0 in the A.G. Leipzig II catalog. He also refers to a Toulouse Observatory Carte du Ceil photographic plate of January 23rd, 1906, on which the red star is not visible, which we were also unable to locate.

Using the Strasbourg Astronomical Data Centre's CDS Portal, we found images from 1954, 1991, and 1997 showing not only the brighter of the red pair, but the fainter one as well (Figure 5). In addition, Wilfried Knapp imaged the star using a remote telescope (Figure 6 ), which clearly showed two stars at the location.

In Jonckheere's account of J 3101 in Figure 4, after referring to the Carte du Ciel plate, the next to last sentence reads: "Therefore the red star probably has a color index higher than +4 ." Bill Hartkopf pointed us toward Simbad's data on the star where we found a B value of 13.55 and a V value of 9.21 , resulting in a color index of 4.34 , which confirms Jonckheere was on the right track with his +4 CI estimate. Simbad also shows a spectral classification of N for the star. Bill Hartkopf mentioned the plates in use for both 1906 Carte du Ceil and 1945 images were blue sensitive and had very poor response in the red, thus explaining the absence for the red J 3101 from those images.

To some degree, that could explain why Jonckheere

Figure 3. AAVSO designation for the red star referred to by Jonckheere in his 1962 catalog entry for J 3101.
didn't mention or refer to the faint secondary located 9 " from the primary. On page three of his 1962 catalog he lists the various telescopes he used during his career, along with the dates he used them. According to that list, when he made his 1945 observation of J 3101 he

# Une Nouvelle Etoile Rouge (J 31O1) 

Par M. Robert Jonckherre

#### Abstract

Au cours de nos recherches d'étoiles doubles nouvelles, nous avons trouvé, le 16 février 1945, une étoile rouge, de magnitude 9,3, qui ne figure pas dans le Neuer Katalog Farbiger Sterne, de F. Krueger, ni, comme variable, dans le Katalog Veränderlicher Sterne für 1943, de H. Schneller.

Les coordonntes de cette étoile, pour 1950, sont : $$
\alpha=7 \mathrm{~h} .13 \mathrm{~m} .0 \mathrm{~s} . \quad \delta=+5^{\circ} 9^{\prime} \mathrm{t}
$$

Contrairement à la Rouge J 2001, qui ne se trouve dans aucun catalogue, malgré sa magnitude qui peut atteindre 8,3, cette nouvelle rouge est une étoile de la Bonner Durchmusterung. C'est la B.D. $+5^{*}{ }^{1606}$, pour laquelle Argelander donne la magnitude 9,5 . Elle a, de plus, été notée, malgré le faible éclat indiqué dans le B.D., sous le $n^{\circ}{ }^{3} 66 \mathrm{t}$ de A.G. Leipzig II, qui lui assigne la magnitude 9,0 . Cette étoile est donc variable.

Aucun de ces catalogues ne fait etat de sa coloration. Son indice de couleur est cependan ttrés grand. Une pose d'une heure en lumierre totale, faite le 9 avril 1945 par M. G. Guigay, avec l'objectif Dogmar Goerzde 18 cm . de l'Observatoire de Marseille, ne donne aucune trace de cette étoile sur la plaque. Elle n'est pas visible non plus sur le cliche $+5^{\circ} \mathrm{n}^{\circ} 54$, du 23 janvier 1906, de la Carte photographique du Ciel de l'Observatoire de Toulouse. Cette étoile rouge a par conséquent un indice de couleur probablement supérieur à +4 . C'est pour cette raison que nous nous y sommes arreté.

Mind the Gap - Jonckheere Double Stars Not Listed in the WDS

Figure 5. 1954, 1991, and 1997 images of $J 3101$ and the white pair to the south of it.
was using the 80 cm ( 31.5 inch ) telescope at Marseille, which Thorel (2005, p. 30) estimates has a 15.8 magnitude limit. Our research shows the secondary with a magnitude of 15.0 (see Table 1), which would seem to put it within visual reach despite the five magnitudes of difference between the two stars. Also contributing to the mystery is Jonckheere's acute vision, which is also well documented by Thorel (2001, pp 3-4 and 5) and was mentioned by Jonckheere himself on page 5 of his 1962 catalog.

At any rate, we found ourselves with a situation in which two historically significant pairs were not listed in the WDS catalog: J 3101 and the white pair to its south. Bill Hartkopf confirmed our guess that J 3101 was left out of the WDS because Jonckheere didn't provide measures for it. Adding somewhat to the confu-

Figure 6. iT27 Image by Wilfried Knapp (stack of 10 images with $2 s$ exposure time). J3101 is the northernmost pair in the image, DOM 2 is south of it. North is at the top, east at the left.
sion is the CCDM catalog's reference to the pair of white stars to the south of the red pair as J 3101 (see the data box below Figure 2).

We asked Bill about the possibility of having both the red and the white pair added to the WDS because of their historical significance. After reviewing all the data, he added the white pair to the WDS with a designation of DOM 2 (DOM refers to Dommanget, the lead author of the CCDM). The red pair was added to the WDS with the designation J 3101. DOM 2 is now WDS $07156+0503$ and J 3101 is $07156+0504$.

With regard to the WDS data, initial coarse measurements for J 3101, based on a GSC2.3 image in Aladin, resulted in a separation of $9.3^{\prime \prime}$ and a PA of $227^{\circ}$ and magnitudes of 9.90 and 15.5. For DOM 2, initial measures are $7.3^{\prime \prime}$ and $204.1^{\circ}$ with magnitudes of 10.62 and 14.69 , which are based on 1995 POSS plates. Our measures, which are shown in Tables 1 and 2, differ somewhat. It should be pointed out that we found the faint magnitudes of both secondaries made measures rather difficult.

## Gaps in the Jonckheere Double Star Catalog

Searches have been run in the WDS Notes Files and Stelle Doppie on all the J Catalog numbers in Table 3. Those catalog numbers for which no data was found in those two sources are identified in the table with the comment "No data found"; those stars will appear in a later report once we've determined their identities. All of the stars in Table 3 which include the comment "Listed in WDS with no coordinates" are shown in Jonckheere's 1962 General Catalog. A search is under way now to locate these.

As a countercheck for the quality of our measures, we used the URAT1 coordinates for DOM 2 (the secondary of J 3101 is not identified in URAT1), resulting in very similar values of 7.387 " for separation and $204.88^{\circ}$ for position angle.
for his invaluable assistance and insight which kept us from straying too far into nebulous territory.

We also want to thank Chris Thuemen for making a copy of Robert Jonckheere's 1962 Catalogue Général de 3350 étoiles doubles de faible éclatobservées de 1906 à 1962 available to us, without which we would have been stumbling around in the dark.

The following tools and resources have been used for this research:

- Aladin Sky Atlas v8.0
- Astrometrica v4.8.2.405
- AstroPlanner v2.2
- CDS Portal
- iTelescope: iT27-700mm CDK with 4531 mm focal length. CCD: FLI PL09000. Resolution 0.53 arcsec/pixel. V-filter. Located in Siding Spring, Australia. Elevation 1122m

# Ludwig Schupmann Observatory Double Star Measures for the Year 2015 

James A. Daley<br>Ludwig Schupmann Observatory<br>New Ipswich, NH

#### Abstract

This report contains measurements in $\theta$ and $\rho$ space for ninety-one (91) pairs. Many of these pairs have published orbits of various grades. Most will require long-term observations (hundreds of years in some cases) to be gauged definitive.

A new (replacement) tailpiece stellar coronagraph is finally operational and was employed in a few large $\Delta \mathrm{m}$ observations reported here. The new design features a $60 \%$ larger field of view to encompass pairs with separations on the order of 250 seconds of arc with the primary centered in the field. Initial star tests show good images, but for the very corners of the CCD frame. Ray trace results indicate low field distortion (well under 0.1\%). This coronagraph is also more mechanically robust than the Ludwig Schupmann Observatory (LSO) package previously reported in this journal (Daley 2007). See photo Figure 1.

## Introduction

After a two year (2013-2014) "rest" period, double star observations have resumed at LSO. The telescope used for the measures reported here has remained unchanged and is described in past JDSO articles (see most recently, Daley 2012). Briefly, the instrument is a color-free 9 inch $\mathrm{f} / 11.1$ Schupmann Medial used with a Barlow lens to provide an effective focal length (FL) of 286.34 inches. Atmospheric dispersion is easily compensated with the Schupmann design. The (now vintage) CCD detector employed in the measurements was made by Santa Barbara Instrument Group, model ST-7 XE.

Plate scale calibration is performed with a normal incidence coarse objective-grating. A single star of about 2 magnitude is imaged through the grating. To accurately define the wavelength, a 10.0 nm bandwidth interference filter, centered at 589.0 nm , is placed normal to the beam just below the Barlow entrance lens. The grating has bars and spaces of equal widths (about 1 cm ), thus diffracting only odd orders. Usually the image spacing measurement is made between the plus and minus $5^{\text {th }}$ order. The focal length parameter is adjusted such that the order spacing (in seconds of arc) agrees with that predicted by the grating formula
(Jones 1979). After many grating images are averaged, the determined FL value is entered in the system parameters as the working value. The overwhelming advantage of this method of plate scale calibration is that it is independent of the pairs we measure and is also free of tilt anisoplanicity (atmospheric unshared-path angle noise).

## The Measures

Data are listed in the conventional way. From left to right: WDS identifier (epoch-2000 RA\&Dec), discoverer designation, decimal date of observation, LSO position angle in degrees, LSO separation in seconds of arc, number of nights object was observed, and a notes column with incidental information or a note number for detailed notes appearing at the end of this report.

Almost all measures are the mean of $8-12$ sharp images. Position angle corrections are determined by a full-field drift image. The doubles are measured (centroid to centroid) using the camera in its native astrometry mode.

## Ludwig Schupmann Observatory Double Star Measures for the Year 2015

Figure 1. A photo of LSOs new stellar coronagraph. A Lyot stop is incorporated and is easily accessed by removing the screws seen near the barrel's mid-point. The telescope is focused on the field lens/occulting mask seen at the left. The CCD bolt-up flange is to the far right.

## Ludwig Schupmann Observatory Double Star Measures for the Year 2015

## Notes to Table 1

1. STI2051: This is a fine example of a dM4-DA (white dwarf) binary. It is visually observable with a 7 inch telescope under really dark skies. With my 9 inch medial both the primary and the secondary are visually pretty easy. CCD exposures run about 5 seconds for a high signal to noise ratio.
I am unaware of a published orbit for Stein $2051{ }^{1}$ despite an orbital arc measuring about 80 degrees. In my opinion, no other binary deserves a preliminary orbit more than this pair. Its astrophysical importance has been recognized for some time. That said, ongoing accurate CCD measures of STI2051 by amateurs will bevaluable indeed.
2. FRH 1AH (Capella): Note that this pair was measured at LSO in 2014. The measure was to judge the practicality of measuring extra-wide doubles with a classic Schmidt camera. The Schmidt was manufactured at LSO and incorporates the observatory's ST-7 CCD. The FOV is over $0.5^{\circ}$ on the short axis of the CCD frame. The camera aperture is 6 inches and operates at f/3.3. A 6 inch objective-prism was also made for the Schmidt for obtaining double star spectra: but that's another story! The measure itself indicates a position angle increase of $0.8^{\circ}$ since discovery (1895) with very little, if any, change in separation.
3. ST 3HL: Popularly known as Capella H, this close pair orbits Capella with a period probably in the thousands of years (see note 2 above)! HL is not an easy pair to measure with a small telescope. Its faintness along with a magnitude difference of over 3 mags provides the observer a challenge even with a CCD camera. Because the binary is in a critical (outermost) part of its orbit, many measures will be required for at least the next 30 years to better define the ellipse.
The fixed reference star mentioned in the LSO report (Daley 2009) was also measured and we see a large change, as follows: H Ref 2009.173 ( $\theta=56.1, \rho=$ 13.65), H Ref $2015.249(\theta=46.1, \rho=15.10)$. The thought here (given continued observations of H Ref) is that it may help future observers determine the close pair's center of mass.
4. AGC 1AB: Sirius and its white dwarf companion are now separated enough to be observed with a fine 6 inch refractor under the best seeing conditions. Blocking the primary star with a narrow aluminum foil bar, tack glued in the plane of the eyepiece field stop, should reveal "B". The CCD measurement listed here was performed with a shaped-pupil aperture mask and the old tailpiece coronagraph, as described in Daley (2014).
5. Superb seeing and very clear skies prevailed for this measure. As such the images were consistently sharp (one second exposure). The measurement is the mean of the eight best images with a standard
${ }^{1}$ Ed. note: There is an orbit (Strand 1977) associated with this pair, but this is an astrometric orbit (23y) of an unresolved close pair associated with the A component.
deviation of $0.12^{\circ}$ in position angle and $0.012^{\prime \prime}$ in separation.
6. STF1196AB,C (弓 Cnc): This measurement is between the optical centroid of the well resolved $A B$ pair and the centroid of the more distant " $C$ ". If $A B$ were unresolved the result should be much the same, allowing observers with smaller instruments (3-5 inch) to make a fine and important measure.
7. STF1540AB (83 Leo): In addition to the measurement importance itself, wide, slow moving pairs such as this may, for the critical user, provide a test of LSOs measurement precision. Small systematic errors may then be used as a multiplier applied to various pairs reported here. Other such wide pairs are to be found in this report. In general, using these pairs for that purpose presupposes the user has exact data for the wide pair itself and how it was gotten! You see, it is easy to go in circles.
8. STF1768AB (25 Cvn): A difference in magnitude of two makes this close pair difficult. As with all such pairs, seeing must be near perfect. Luck prevailed and 12 nice, sharply resolved, images were captured for this measure.
9. STF1877AB (o Boo): A favorite for testing telescopes, this binary has moved about $22^{\circ}$ since discovery. LSO data show no sensible $\theta$ change in 15 years with the separation value remaining identical.
10. ROE 75: Very slow moving pair. Since 1993, the double has opened about 0.2 " with a $\theta$ change of perhaps $1^{\circ}$.
11. ES 492: The WDS listed magnitudes infer a V-band $\Delta \mathrm{m}$ of 0.36 . The LSO $\Delta \mathrm{m}$ value for an unfiltered CCD is 0.84 which is roughly an R -band measure. Four high signal-to-noise images were averaged for this $\Delta \mathrm{m}$ result.
12. STF2570AB,C: The primary is AGC 10. The LSO measure is in better agreement with Burnham's Celestial Handbook 1955 listing than the WDS 2001 value ${ }^{2}$. The pair is opening slowly.
13. STF2579AB ( $\delta$ Cyg): The brightness difference makes this binary a stunning sight in good seeing. In the LSO 9 inch the view is unforgettable, giving the impression of true binarity like no other pair I know.
14. STF2822AB ( $\mu \mathrm{Cyg}$ ): This is now a moderately fast moving binary. It is closing with a position angle rate of about 0.9 degrees/yr.
15. ES 521DE: Very few measures, but this pair appears to be physical, as the secondary motion is slightly concave to the primary. Additionally, the pair looks to have common proper motion.
16. STF2863AB: LSO measures show a PA standstill for the past 15 years, however the separation is slightly but smoothly increasing. The speckle pair MCA 69Aa,Ab may cause slight irregular motion, although perhaps not of this magnitude.
[^0]
## Ludwig Schupmann Observatory Double Star Measures for the Year 2015

17. WOR 11: A sparsely measured, but astrophysically important red dwarf pair. I regret not regularly observing this fast moving binary over the last 15 years. The object is faint and difficult, thus providing the amateur a nice challenge.
18. BU 290AB (34 Peg): This is one of the most difficult pairs for the small telescope due to a rather large $\Delta \mathrm{m}$ of about 6.7. Understandably, the binary is under measured. This double has a (preliminary) published orbit (Hale 1994) which can be accessed on the WDS Double Star CD 2006.5. When the LSO data is compared to the orbit diagram, it lies well outside the maximum separation region of the ellipse. The position angle has increased about $2^{\circ}$ since 1990. To mitigate diffraction veiling, the binary was imaged using a square pupil mask with an opening of 6 inches on a side. Utilizing a log display helped "bring out" the faint secondary very nicely. A 15-20 second exposure with an R-band filter seemed to work best. Pixel binning ( $2 \times 2$ ) shortened the required exposure, but naturally degraded the measurement precision, thus this mode was not used in the measurements.
19. STF3050AB: As with BU 290AB above, a significant departure from the published orbit (Starikova 1977) is observed, the data point lying outside the orbit plot in a sharply turning region of the ellipse. Photometric $\Delta \mathrm{m}$ measures in R-band were also made. Six images were measured giving a mean value of 0.18 . The effective filter center wavelength is 661.0 nm and the half bandwith is 195.0 nm .

# STT Doubles with Large $\mathbf{\Delta M}$ - Part V: Aquila, Delphinus, Cygnus, Aquarius 

Wilfried R.A. Knapp<br>Vienna, Austria<br>wilfried.knapp@gmail.com

John Nanson<br>Star Splitters Double Star Blog<br>Manzanita, Oregon<br>jnanson@nehalemtel.net

#### Abstract

The results of visual double star observing sessions suggested a pattern for STT doubles with large $\Delta \mathrm{M}$ of being harder to resolve than would be expected based on the WDS catalog data. It was felt this might be a problem with expectations on one hand, and on the other might be an indication of a need for new precise measurements, so we decided to take a closer look at a selected sample of STT doubles and do some research. We found that, as in the other constellations covered so far (Gem, Leo, UMa etc.), at least several of the selected objects in Aql, Del, Cyg and Aqr show parameters quite different from the current WDS data

## 1. Introduction

As a follow up to our STT reports so far, we continued in the constellations of Aquila, Delphinus, Cygnus, and Aquarius, which contained (with the exception of 3 multiples in Cyg covered in a separate report) 14 objects from our list (see Table 1). All values are based on WDS data as of the begin of 2016 .

## 2. Further Research

Following the procedure for the earlier parts of our report we concluded again that the best approach would be to check historical data on all objects, observe them visually with the target of comparing with the existing data and obtain as many images as possible suitable for photometry.

### 2.1 Historical Research and Catalog Comparisons

Of the eleven stars in this survey, three of them have notable aspects worth further investigation. Three

## STT Doubles with Large $\mathbf{\Delta M}$ - Part V: Aquila, Delphinus, Cygnus, Aquarius

main research sources were used for this section of the paper, the first of which was W.J. Hussey's Micrometrical Observations of the Double Stars Discovered at Pulkovo, published in 1901, which provided preliminary historical information on each of the stars. Hussey's book includes his observations and measures of all the stars originally listed in Otto Wilhelm Struve's 1845 Pulkovo Catalog, as well as data beginning with the date of first measure and continuing through the following years up to 1900. That data, plus inclusion of the background for the Pulkovo Catalog, makes Hussey's book a valuable source of reference. Also consulted was S.W. Burnham's A General Catalogue of Double Stars Within $121^{\circ}$ of the North Pole, Part I and Part II, for information on STT 381 and STT 460. In addition, Bill Hartkopf of the USNO graciously provided the text file for STT 460.

STT 381 (Aql) The intriguing aspect of STT 381 is Hussey's statement that that pair was dropped from the second edition of the Pulkovo catalog because "the companion was regarded as too faint for exact measurement with the 15 -inch Pulkowa telescope." According to Hussey's account of STT 381, the pair was first measured by Johann Heinrich Mädler in 1847 at $8^{\circ}$ and 15.74 ", but no magnitudes are shown. However Burnham, in Part I of his 1906 Catalog, lists an 1843 measure by Mädler of $7.5^{\circ}$ and 15.79 " with magnitudes of 7 and 11 (see Figure 2). Burnham also notes the exclusion of STT 381 from the second Pulkovo catalog, and includes a remark that the secondary wasn't seen by Dembowski in 1865, but notes he (Burnham) found it easy in 1876 with his six inch refractor. Hussey shows magnitudes of 8.0 and 12.0 for the pair in 1899, and Burnham lists them at 7.2 and 11.7 in 1900 (See Figure 2). The WDS shows a more narrow range of 8.0 and 11.20 for the pair. Our photometry resulted in a magnitude of 12.396 for B , but our result for A of 7.775 was hampered by the brightness of A relative to B . We can add that visual observations of B were difficult with a six inch refractor and a 9.25 inch SCT.

STT 409 (Del) This pair was first measured in 1843 by Mädler at $83.6^{\circ}$ and 16.33 ". Hussey notes

Otto Struve dropped STT 409 from the second edition of the Pulkovo catalog because the separation exceeded the 16 " separation limit set for pairs with secondaries fainter than ninth magnitude. That limit was set by F.G.W. Struve, who began the survey in 1841 and a month later turned it over to his son, Otto (Hussey, 1901, p. 16). There's a tenth magnitude C companion which was added in 1894 by S. Glasenapp.

STT 460 (Aqr) The component of STT 460 which is now designated as C in the WDS was first measured in 1845 by Mädler at $53.9^{\circ}$ and $15^{\prime \prime}$. The second component, now designated as B in the WDS, was added in 1849 by Otto Struve, with measures of $355.7^{\circ}$ and $5.68^{\prime \prime}$. However, when the 1850 revision of the Pulkovo Catalog was published, it listed the two components of STT 460 at distances of 1.5 " and 7.3 ". That set off a search by S.W. Burnham (Burnham, 1875) with his six inch refractor which failed to turn up a component at that distance. Hussey also searched for it with the 36 inch Lick refractor on two night in 1898 (Hussey, 1901, p. 182) and was unable to detect a component in the 1.5 " range. It appears the 1.5 " distance published in the 1850 catalog was very likely a misprint of 15 ".

The relative positions of the three components have changed rapidly since their discoveries in 1845 and 1849. The AB pair's initial measures ( $355.7^{\circ}$ and $5.68^{\prime \prime}$ ) are virtually unrecognizable when compared to the current WDS measures (2003) of $340^{\circ}$ and $13.80^{\prime \prime}$; our measures for the pair are $339.8^{\circ}$ and $14.47^{\prime \prime}$. The AC pair, first measured at $53.9^{\circ}$ and $15^{\prime \prime}$, is listed in the WDS at $30^{\circ}$ and $18.80^{\prime \prime}$ (also from 2003); our measures are $29.5^{\circ}$ and $19.33^{\prime \prime}$. The WDS text file data for AB and AC displayed in Figure 2.2 highlights the consistent increases in the separations of both pairs, along with steady changes in their position angles.

The proper motion overlay in Figure 3 clearly illustrates the disparate motion of each of the three stars which has resulted in the increasing separation of the components of STT 460. Apart from the B component, the proper motions are not especially high, but as the image shows, each of the three stars is moving away
(Continued on page 476)
9540. $0 \Sigma{ }^{3}{ }^{81 \mathrm{r}} \mathrm{rej}$. Rejected in second edition of the ${ }^{37}{ }^{23}$ Poulkowa Catalogue. Companion not visible to $\Delta$ in 1865 ; easy with 6 -inch in 1876 . No change shown by the later measures.

Figure 2. From Burnham's 1906 Catalog of Double Stars, Part II, p. 855.

Figure 3. Proper Motion of STT 460 Components super-imposed on Aladin image using UCAC4 data.
from the others. (The arrows for B and C, which were added to the image, are not to scale. The arrow for A comes from Simbad's database).

### 2.2 Visual Observations

Both John Nanson and Wilfried Knapp made visual observations of the stars included in this report. John used a $152 \mathrm{~mm} \mathrm{f} / 10$ refractor, while Wilfried utilized a 140 mm refractor and a 235 mm SCT, as well as a masking device to evaluate what could be seen at lesser apertures.

STT 362 (Aql): John looked at STT 362 twice and found the B component to be more difficult than expected given the 7.60 " separation and the $3.66 \mathrm{mag}-$ nitudes of difference with the primary. B varied from an elongated smear to a definite point of light for very brief moments, making it impossible to estimate its magnitude. The general impression was B is fainter than the 11.93 shown for it in the WDS. Wilfried also looked at STT 362 twice and was able to split the AB pair on the second observation, but came to no conclusion on magnitude. Neither observer was able to catch sight of the C component. Wilfried was able to see nearby stars in the 13.5 magnitude range, which sug-
gests C is fainter than that magnitude.
STT 368 (Aql): Wilfried observed STT 368 twice and apart from seeing an elongation of the $A B$ pair, was unable to resolve the secondary. He caught a glimpse of C during the second observation at 100x, but was unable to catch sight of it again at higher magnifications, suggesting it may be significantly fainter than the WDS magnitude of 11.3. John resolved the AB pair at 253 x and 380 x with the six inch refractor during the one observation he made. He was able to see the C component clearly enough at 380 x to compare it with three other stars, and found the star with a Vmag of 11.589 was closest in magnitude to C.

STT 381 (Aql): John observed STT 381 once and found the B component was tougher than expected for a pair with a separation of 14.7"and a magnitude difference of 3.2. The one comparison star he found had an incorrect Vmag of 10.298 (UCAC4 471108123), but the f.mag for that star of 12.412 was more in line with the visual difficulty. Wilfried observed this pair twice and resolved B on the second attempt. He found a comparison star with an f.mag of 11.659 was a

## STT Doubles with Large $\mathbf{\Delta M}$ - Part V: Aquila, Delphinus, Cygnus, Aquarius

bit brighter than $B$, again suggesting $B$ is fainter than the WDS magnitude of 11.2.

STT 409 (Del): Wilfried observed STT 409 once and was able to see B with a limiting aperture of 58 mm , suggesting the WDS magnitude of 10.20 is correct. John also made one observation and found $B$ was slightly brighter than a comparison star which was a magnitude fainter than the WDS value. Both observers were able to see C easily.

STT 460 (Aqr): John observed STT 460 several times and found it to be a real visual gem. Both the B and C components were very obvious on first sight, suggesting they're both brighter than the WDS values of 12.80 and 12.10 , respectively. Nearby comparison stars suggested a magnitude for B of about 11.3. The C component appeared a bit brighter than B , which suggests a magnitude in the 10.6 range.

STT 532 (Aql): Wilfried observed STT 532 twice and was able to resolve B with averted vision during the first observation at a magnification of 470x. He found a nearby comparison star with an f.mag of 11.778 was similar in brightness to $B$, suggesting the WDS value of 11.90 is close. John observed STT 532 once and only managed a few fleeting glimpses of B, which were not enough to come to a conclusion on its magnitude.

STT 374 (Cyg): John observed STT 374 once and found the B component was very similar in magnitude to three comparison stars with Vmags ranging from 10.9 to 11.1 , agreeing with the WDS value of 11.1. Wilfried looked at STT 374 twice and with the aid of the masking device also confirmed the WDS value.

STT 412 (Cyg): Wilfred viewed STT 412 twice and with the aid of the masking device concluded B is 1.5 magnitudes brighter than the WDS value of 13.1 . John observed STT 412 once and found B was obviously brighter than the WDS value. A close comparison with the 11.22 magnitude C companion showed both B and C to be similar in magnitude, with C being slightly brighter than B. Comparison stars indicated the WDS magnitude for C is about right, leading to the conclusion that B is in the 11.5 to 11.8 magnitude range since it appears to about half a magnitude fainter than C .

STT 420 (Cyg): John observed this pair once and found B was very obvious at 190x in the six inch refractor, and also could see it at 152 x . Given the 5.4" separation and 4.0 magnitude difference between primary and secondary, the WDS value for B of 10.7 seems to be about right. Wilfried looked at STT 420 twice but was unable to detect B due to poor seeing conditions.

STT 427 (Cyg): Wilfried observed this pair once
but was unable to resolve the two stars with a 140 mm refractor. John observed it once with a 152 mm refractor and was able to see the secondary at 152 x and 253 x . The difficulty seemed to be about what would be expected given the 4.07 magnitudes of difference and 4.2" separation.

STT 438 (Cyg): John looked at STT 438 twice. Seeing was poor during the first observation, but the secondary was glimpsed briefly a couple of times. During the second attempt, with better seeing, the secondary could be seen as a bump on the edge of the primary at 152 x and 253 x . A magnitude estimate wasn't possible, but given the three magnitudes of difference and the 2.3 " separation, the visual difficulty was about what would be expected. Wilfried also looked at this pair twice. During the first observation, the secondary could be seen at 200x with the aperture reduced to 117 mm , which would seem to confirm the WDS magnitude of 10.3 for B . Poor seeing during the second attempt prevented catching sight of the secondary.

### 2.3 Photometry and Astrometry Results

Several hundred images taken with iTelescope remote telescopes were in a first step plate solved and stacked with AAVSO VPhot. The stacked images were then plate solved with Astrometrica with UCAC4 reference stars with Vmags in the range 10.5 to 14.5 mag . The RA/Dec coordinates resulting from plate solving with UCAC4 reference stars in the 10.5 to 14.5 mag range were used to calculate Sep and PA using the formula provided by R. Buchheim (2008). Err_Sep is calculated as $\operatorname{SQRT}\left(\mathrm{dRA}^{\wedge} 2+\mathrm{dSep}^{\wedge} 2\right)$ with $\mathrm{dR} \overline{\mathrm{A}}$ and dDec as average RA and Dec plate solving errors. Err_PA is the error estimation for PA calculated as arctan (Err_Sep/Sep) in degrees assuming the worst case that Err_Sep points in the right angle to the direction of the separation means perpendicular to the separation vector. Mag is the photometry result based on UCAC4 reference stars with Vmags between 10.5 and 14.5mag. Err_Mag is calculated as

$$
E r r_{-} M a g=\sqrt{d V_{m a g}^{2}+\left[2.5 \log _{10}\left(1+\frac{1}{S N R}\right)\right]^{2}}
$$

with $d V m a g$ as the average Vmag error over all used reference stars and $S N R$ is the signal to noise ratio for the given star. The results are shown in Table 2 (dRA, dDec , dVmag and SNR not given due to space restrictions).

## Summary

Tables 3 and 4 below compare the final results of

## STT Doubles with Large $\mathbf{\Delta M}$ - Part V: Aquila, Delphinus, Cygnus, Aquarius

Table 2. Photometry and astrometry results for the selected STT objects. Date is the Bessel epoch in 2015 and N is the number of images (usually with 1s exposure time) used for the reported values. iT in the Notes column indicates the telescope used with number of images and exposure time given (Specifications of the used telescopes: See Acknowledgements). The average results over all used images are given in the line below the individual stacks in red and bold. The error estimation over all used images is calculated as root mean square over the individual Err values. The $N$ column in the summary line gives the total number of images used and Date the average Bessel epoch.

## STT Doubles with Large $\mathbf{\Delta M}$ - Part V: Aquila, Delphinus, Cygnus, Aquarius

Table 2 (continued). Photometry and astrometry results for the selected STT objects. Date is the Bessel epoch in 2015 and $N$ is the number of images (usually with $1 s$ exposure time) used for the reported values. iT in the Notes column indicates the telescope used with number of images and exposure time given (Specifications of the used telescopes: See Acknowledgements). The average results over all used images are given in the line below the individual stacks in red and bold. The error estimation over all used images is calculated as root mean square over the individual Err values. The $N$ column in the summary line gives the total number of images used and Date the average Bessel epoch.

## STT Doubles with Large $\mathbf{\Delta M}$ - Part V: Aquila, Delphinus, Cygnus, Aquarius

Table 2 (conclusion). Photometry and astrometry results for the selected STT objects. Date is the Bessel epoch in 2015 and $N$ is the number of images (usually with $1 s$ exposure time) used for the reported values. iT in the Notes column indicates the telescope used with number of images and exposure time given (Specifications of the used telescopes: See Acknowledgements). The average results over all used images are given in the line below the individual stacks in red and bold. The error estimation over all used images is calculated as root mean square over the individual Err values. The $N$ column in the summary line gives the total number of images used and Date the average Bessel epoch.

Figure 5. Not as close as STT438, but still difficult to resolve with the equipment currently available to us - again iT18 provided a hint of resolution of this pair with a very bright primary

## STT Doubles with Large $\mathbf{\Delta M}$ - Part V: Aquila, Delphinus, Cygnus, Aquarius

(Continued from page 477)
our research with the WDS data that was current at the time we began working on our current group of stars.

In Table 3 the results of our photometry have been averaged for each star. Because we're aware that both the NOMAD-1 and the UCAC4 catalogs are frequently consulted when making WDS evaluations of magnitudes changes, the data from those catalogs has also been included for each of the stars.

Red type has been used in Tables 3 and 4 to call attention to significant differences from the WDS data. With regard to Table 3, those magnitudes that differ by two tenths of a magnitude or more from the WDS values have been highlighted. In Table 4, differences in separation in excess of two-tenths of an arc second are highlighted, as are all position angles which differ by more than a degree.

Subsequent to our measures, as a quality check for our astrometry results we turned to the URAT1 catalog for the most recent precise professional measurements available. We used its coordinates to calculate the Sep
and PA for all objects in this report for which URAT1 data was available and compared these values with our results, which are shown in Table 5.

## Acknowledgements:

The following tools and resources have been used for this research:

- Washington Double Star Catalog as data source for the selected objects
- iTelescope: Images were taken with
- iT24: 610 mm CDK with 3962 mm focal length. CCD: FLI-PL09000. Resolution $0.62 \mathrm{arcsec} /$ pixel. V-filter. Located in Auberry, California. Elevation 1405m
- iT11: 510 mm CDK with 2280 mm focal length. CCD: FLI ProLine PL11002M. Resolution 0.81 arcsec/pixel. B- and V-Filter. Located in Mayhill, New Mexico. Elevation 2225m
- iT18: 318 mm CDK with 2541 mm focal length. CCD: SBIG-STXL-6303E. Resolution 0.73

# Speckle Interferometry of Close Visual Binaries with a 280 mm Reflector and an EM-CCD 

J. Sérot<br>¡ocelyn.serot@free.fr

#### Abstract

This paper presents the measurements of 319 visual binary stars obtained between Sep 2015 and Feb 2016 with an 11" reflector telescope and an EM-CCD camera, using speckle interferometry.

## 1. Introduction

This paper is an addition to the one published in the september special issue of JDSO [1]. It presents the measurements of 319 visual binary stars obtained between Sep 2015 and Feb 2016 with an 280 mm reflector telescope and an EM-CCD camera. The total number of measurements is 323 , concerning 319 binaries with magnitudes and separation ranging between 4.4 and 11.3 and 0.4 ' and 1,5 ' respectively.

## 2. Equipment

The equipement has already been described in [1]. We therefore only recall its main characteristics. The telescope is a 280 mm Schmidt-Cassegrain reflector (Celestron C11) and the camera a Raptor Kite EMCCD [2]. The native focal length of the telescope ( $2.8 \mathrm{~m}, \mathrm{~F} / \mathrm{D}=10$ ) is augmented to 17 m using eyepiece projection - which provides more flexible way to adapt the resulting focal length than the telecentric amplifier described in [1] - leading to a plate scale of $0.11 " /$ pixel $($ pixel size $=10 \mu \mathrm{~m})$.

An atmospheric dispersion corrector, using a simple pair of Risley prisms [3] is inserted in the optical path to compensate for the effects of atmospheric dispersion when imaging stars not close to the zenith. An IR-cut filter (rejecting all wavelength above 700 nm ) is also systematically used.

## 3. Image acquisition and reduction

Acquisition is carried out with the Genika Astro software [4]. For each star 1500 images are acquired. No deconvolution star is used. Exposure time for individual images range from 10 to 40 ms typically and the EM gain of the camera - except for the brightest stars -
is set to $90 \%$ of the maximum (this value has been determined experimentally : above the SNR is simply too low.

Precise on-sky scale and orientation calibration is performed each observing night using a pair of calibrating stars taken from a list available from the SAF website [5].

Selection of the binaries to measure is carried out using the latest, online version of the WDS catalog [6] with the help of the $W d s P i c k$ software introduced in [1]. This software now has the possibility to compute and display the required ADC setting for a given star (knowing the coordinates of this star, the local sideral time and the correction curve of the ADC - which has been determined experimentally.

For practical reasons target stars are systematically observed 1-2 h before the local meridian (observing past the meridian requires a complete mount reversal which is very unpractical). The telescope shed and the ADC range respectively limit the visibility to stars having a declination between $0^{\circ}$ and $60^{\circ}$.

Given these ranges, the selection of target stars is based on the magnitude of the components, their last known separation, the total number of measurements and the date of the latest measure as reported in [6].

Image reduction is carried out with the Reduc software [7]. Pre-processing (dark substraction, cropping, quality sorting and power spectrum computation) is carried out automatically, in batch mode, the two only steps requiring manual intervention being the final selection of the best images for obtaining lucky images by co-addition (when possible) on the one hand and the measurement of the peak position on the autocorrelogram on the other hand. As described in [1], the former

Figure 3. Distribution of measurements according to the separation of components.
is mainly used to overcome the quadrant ambiguity of the other method and, exceptionnaly, when the other method fails because the compagnon is too faint.

## 4. Results

The reported measurements have been obtained

Figure 4. O-C residuals plotted in rectangular coordinates for pairs having an orbit graded 1-2. The dash-lined square represents a pixel in the used instrumental setup.
during 21 nights, between 2015-09-09 and 2016-02-05. The total number is 323 mesures, concerning 319 binaries (among these, 66 have a published orbit.

Figures 1, 2, and 3 show the distribution of all measurements according to the magnitude and separation of components.

These measures are summarized in Table 1, following the habitual JDSO format.

We also report in Table 2. on 18 stars which were either perceived as binaries, but cannot reliably measured because their separation was too close ( $<0.4^{\prime \prime}$ typically) or were viewed as simple.

For three pairs our measurement of the position angle exhibits a quadrant inversion compared to the latest one reported in [6]. Our observations are reported in Figure 5 For WDS 21521+2748, the inversion could have been induced by the small difference in magnitude. For WDS 03354+3529 and WDS 02018+4040, the significantly larger difference in magnitude ( 0.5 and 1.1 respectively) rules out this explanation. Note that for the latters, the number of observations is relatively small (18 and 8 respectively).

For pairs having a known orbit graded 1 or 2, Table 3 gives the O-C residuals, computed from the ephemerids published in the 6th Orbit Catalog [8]. These residuals are plotted in Figure 4 using a polar to rectangular conversion, in order to assess the precision of the measurements.

The details of all measurements (including images) can be obtained online at [9].

Table Notes:

1. O-C given in Tab 3
2. Direct measure (no AC computed)
3. $\mathrm{AB}=\mathrm{STT} 531$
4. $A B=A 1061 A B=A 1061$
5. Possible quadrant inversion wrt. WDS (see Fig. 5)
6. $\mathrm{AC}=\mathrm{STF} 439$
7. $A B=B \cup 880$
8. Direct measure by surface adjustment (Surface algorithm in Reduc)

## Speckle Interferometry of Close Visual Binaries with a 280 mm Reflector and an EM-CCD

(Continued from page 489)

## Acknowledgments

This research has made use of the Washington Double Star and 6th Orbit catalogs maintained at the U.S. Naval Observatory. Data reduction was carried out using the Reduc software (v 5.0) developed and maintained by F. Losse.

# Astronomical Association of Queensland Measurement of Seven Neglected Double Stars 

Graeme Jenkinson<br>Astronomical Association of Queensland.<br>bluestars@iprimus.com.au

#### Abstract

This paper presents the results of a mid 2015 program of photographic measurements of seven southern multiple stars.

## Introduction

These latest results are part of an ongoing program commenced in 2008 by the Double Star Section of the Astronomical Association of Queensland. The target stars were selected from the Washington Double Star Catalog (WDSC) and were observed in Queensland from a latitude of approximately $27^{\circ} \mathrm{S}$.

## Method

Once obtained with the equipment described below, the images were analysed using the astrometric double star program REDUC (Losse, 2008). Approximately 10 stacked images of each target were taken per night for seven nights and the results averaged to obtain measures of separation and position angle with sufficient confidence.

Full details of the method are given in NapierMunn and Jenkinson (2009). Some recent work on the errors inherent in the method is described in NapierMunn and Jenkinson (2014). As proficiency has grown in the use of this equipment with the 400 mm reflector, close doubles with considerable magnitude difference between the components have been successfully measured.

## Results

For all of the systems shown in Tables 2 through 8, the WDSC information is first reproduced, showing the epoch 2000 position, magnitudes, separation, PA, and the last recorded measurement. The new measurements are then given in tabular form, including the mean and standard deviation and $95 \%$ confidence limits. Any uncertainties between the images and the last recorded measurements are discussed. Finally a conclusion is given as to whether any movement of the component stars has occurred in PA or separation, based on the Pvalue for the $t$-test comparing the new mean values with the cataloged value ( $\mathrm{P}<0.05$ is considered as evidence of change).

## Summary

The images were obtained using a Meade DSI CCD camera in conjunction with an equatorially mounted 400 mm F4.5 reflector. Image processing was carried out using Losse's REDUC software.

The mean $95 \%$ confidence intervals for the new measures were $\pm 0.944^{\circ}$ in PA and $\pm 0.193^{\prime \prime}$ in separation. The results are summarized in Table 1.

Questions, comments, or submissions may be directed torclark@southalabama.edu or to rmollise@bellsouth.net

The Journal of Double Star Observations (JDSO) publishes articles on any and all aspects of astronomy involving double and binary stars. The $J D S O$ is especially interested in observations made by amateur astronomers. Submitted articles announcing measurements, discoveries, or conclusions about double or binary stars may undergo a peer review. This means that a paper submitted by an amateur astronomer will be reviewed by other amateur astronomers doing similar work.

Not all articles will undergo a peer review. Articles that are of more general interest but that have little new scientific content such as articles generally describing double stars, observing sessions, star parties, etc. will not be refereed.

Submitted manuscripts must be original, unpublished material and written in English. They should contain an abstract and a short description or biography ( 2 or 3 sentences) of the author(s). For more information about format of submitted articles, please see our web site at http://www.jdso.org

Submissions should be made electronically via e-mail to rclark@southalabama.edu or to rmolise@bellsouth.net. Articles should be attached to the email in Microsoft Word, Word Perfect, Open Office, or text format. All images should be in jpg or fits format.
